

Concurrency and Synchronisation

1

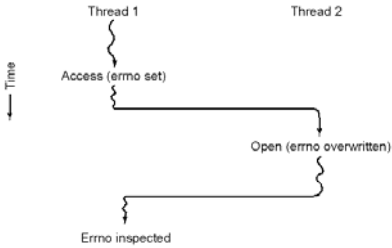

Textbook

- Sections 2.3 & 2.4

2

Making Single-Threaded Code Multithreaded

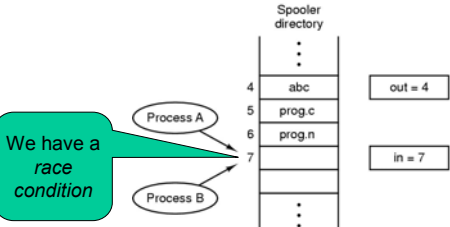

Conflicts between threads over the use of a global variable

4

Inter- Thread and Process Communication

Two processes want to access shared memory at same time

4

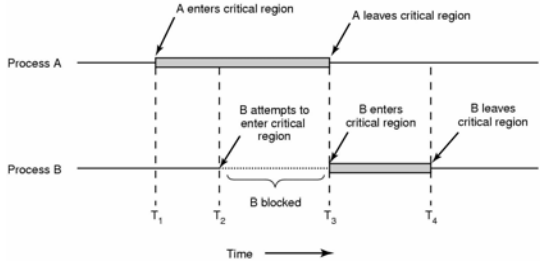

Critical Region

- We can control access to the shared resource by controlling access to the code that accesses the resource.
- ⇒ A *critical region* is a region of code where shared resources are accessed.
 - Variables, memory, files, etc...
- Uncoordinated entry to the critical region results in a race condition
 - ⇒ Incorrect behaviour, deadlock, lost work,...

5

Critical Regions

Mutual exclusion using critical regions

6

Critical Regions

Also called *critical sections*

Conditions required of any solution to the critical region problem

- Mutual Exclusion:
 - No two processes simultaneously in critical region
- No assumptions made about speeds or numbers of CPUs
- Progress
 - No process running outside its critical region may block another process
- Bounded
 - No process must wait forever to enter its critical region

7

A non-solution

- A lock variable
 - If lock == 1,
 - somebody is in the critical section and we must wait
 - If lock == 0,
 - nobody is in the critical section and we are free to enter

8

A non-solution

```
while (TRUE) {           while (TRUE) {
    while (lock == 1);    while (lock == 1);
    lock = 1;             lock = 1;
    critical();           critical();
    lock = 0;             lock = 0;
    non_critical();       non_critical();
}                          }
```

9

A problematic execution sequence

```
while (TRUE) {           while (TRUE) {
    while (lock == 1);    while (lock == 1);
    lock = 1;             lock = 1;
    critical();           lock = 1;
    lock = 0;             critical();
    non_critical();       lock = 0;
}                          non_critical();
                          lock = 0;
                          non_critical();
                          }
```

10

Observation

- Unfortunately, it is usually easier to show something does not work, than it is to prove that it does work.
 - Ideally, we'd like to prove, or at least informally demonstrate, that our solutions work.

11

Mutual Exclusion by Taking Turns

```
while (TRUE) {           while (TRUE) {
    while (turn != 0)     while (turn != 1)
        /* loop */;      /* loop */;
    critical_region();    critical_region();
    turn = 1;             turn = 0;
    noncritical_region(); noncritical_region();
}                          }
```

(a) (b)

Proposed solution to critical region problem
(a) Process 0. (b) Process 1.

12

Mutual Exclusion by Taking Turns

- Works due to *strict alternation*
 - Each process takes turns
- Cons
 - Busy waiting
 - Process must wait its turn even while the other process is doing something else.
 - With many processes, must wait for everyone to have a turn
 - Does not guarantee progress if a process no longer needs a turn.
 - Poor solution when processes require the critical section at differing rates

Peterson's Solution

- See the textbook

Mutual Exclusion by Disabling Interrupts

- Before entering a critical region, disable interrupts
- After leaving the critical region, enable interrupts
- Pros
 - simple
- Cons
 - Only available in the kernel
 - Blocks everybody else, even with no contention
 - Slows interrupt response time
 - Does not work on a multiprocessor

Hardware Support for mutual exclusion

- Test and set instruction
 - Can be used to implement lock variables correctly
 - It loads the value of the lock
 - If lock == 0,
 - set the lock to 1
 - return the result 0 – we acquire the lock
 - If lock == 1
 - return 1 – another thread/process has the lock
 - Hardware guarantees that the instruction executes atomically.
 - Atomically: As an indivisible unit.

Mutual Exclusion with Test-and-Set

```
enter_region:
TSL REGISTER,LOCK      | copy lock to register and set lock to 1
CMP REGISTER,#0        | was lock zero?
JNE enter_region       | if it was non zero, lock was set, so loop
RET | return to caller; critical region entered
```

```
leave_region:
MOVE LOCK,#0           | store a 0 in lock
RET | return to caller
```

Entering and leaving a critical region using the TSL instruction

Test-and-Set

- Pros
 - Simple (easy to show it's correct)
 - Available at user-level
 - To any number of processors
 - To implement any number of lock variables
- Cons
 - Busy waits (also termed a *spin lock*)
 - Consumes CPU
 - Livelock in the presence of priorities
 - If a low priority process has the lock and a high priority process attempts to get it, the high priority process will busy-wait forever.
 - Starvation is possible when a process leaves its critical section and more than one process is waiting.

Tackling the Busy-Wait Problem

- Sleep / Wakeup
 - The idea
 - When process is waiting for an event, it calls sleep to block, instead of busy waiting.
 - The the event happens, the event generator (another process) calls wakeup to unblock the sleeping process.

The Producer-Consumer Problem

- Also called the *bounded buffer* problem
- A producer produces data items and stores the items in a buffer
- A consumer takes the items out of the buffer and consumes them.

Issues

- We must keep an accurate count of items in buffer
 - Producer
 - can sleep when the buffer is full,
 - and wakeup when there is empty space in the buffer
 - The consumer can call wakeup when it consumes the first entry of the full buffer
 - Consumer
 - Can sleep when the buffer is empty
 - And wake up when there are items available
 - Producer can call wakeup when it adds the first item to the buffer

Pseudo-code for producer and consumer

```

int count = 0;
#define N 4 /* buf size */
prod() {
    while(TRUE) {
        item = produce()
        if (count == N)
            sleep();
        insert_item();
        count++;
        if (count == 1)
            wakeup(con);
    }
}

con() {
    while(TRUE) {
        if (count == 0)
            sleep();
        remove_item();
        count--;
        if (count == N-1)
            wakeup(prod);
    }
}
    
```

Problems

```

int count = 0;
#define N 4 /* buf size */
prod() {
    while(TRUE) {
        item = produce()
        if (count == N)
            sleep();
        insert_item();
        count++;
        if (count == 1)
            wakeup(con);
    }
}

con() {
    while(TRUE) {
        if (count == 0)
            sleep();
        remove_item();
        count--;
        if (count == N-1)
            wakeup(prod);
    }
}
    
```

Concurrent uncontrolled access to the buffer

Problems

```

int count = 0;
#define N 4 /* buf size */
prod() {
    while(TRUE) {
        item = produce()
        if (count == N)
            sleep();
        insert_item();
        count++;
        if (count == 1)
            wakeup(con);
    }
}

con() {
    while(TRUE) {
        if (count == 0)
            sleep();
        remove_item();
        count--;
        if (count == N-1)
            wakeup(prod);
    }
}
    
```

Concurrent uncontrolled access to the counter

Proposed Solution

- Lets use a locking primitive based on test-and-set to protect the concurrent access

Proposed solution?

```

int count = 0;
#define N 4 /* buf size */
prod() {
    while(TRUE) {
        item = produce()
        if (count == N)
            sleep();
        acquire_lock()
        insert_item();
        count++;
        release_lock()
        if (count == 1)
            wakeup(con);
    }
}

con() {
    while(TRUE) {
        if (count == 0)
            sleep();
        acquire_lock()
        remove_item();
        count--;
        release_lock();
        if (count == N-1)
            wakeup(prod);
    }
}
    
```

Problematic execution sequence

```

prod() {
    while(TRUE) {
        item = produce()
        if (count == N)
            sleep();
        acquire_lock()
        insert_item();
        count++;
        release_lock()
        if (count == 1)
            wakeup(con);
    }
}

con() {
    while(TRUE) {
        if (count == 0)
            sleep();
        acquire_lock()
        remove_item();
        count--;
        release_lock();
        if (count == N-1)
            wakeup(prod);
    }
}
    
```

wakeup without a matching sleep is lost

Problem

- The test for *some condition* and actually going to sleep needs to be atomic

- The following does not work

```

acquire_lock()
if (count == N)
    sleep();
release_lock()
    
```

The lock is held while asleep \Rightarrow count will never change

Semaphores

- Dijkstra (1965) introduced two primitives that are more powerful than simple sleep and wakeup alone.
 - P(): *proberen*, from Dutch to *test*.
 - V(): *verhogen*, from Dutch to *increment*.
 - Also called *wait & signal, down & up*.

How do they work

- If a resource is not available, the corresponding semaphore blocks any process *waiting* for the resource
- Blocked processes are put into a process queue maintained by the semaphore (avoids busy waiting!)
- When a process releases a resource, it *signals* this by means of the semaphore
- Signalling resumes a blocked process if there is any
- Wait and signal operations cannot be interrupted
- Complex coordination can be implemented by multiple semaphores

Semaphore Implementation

- Define a semaphore as a record

```
typedef struct {
    int count;
    struct process *L;
} semaphore;
```
- Assume two simple operations:
 - `sleep` suspends the process that invokes it.
 - `wakeup(P)` resumes the execution of a blocked process `P`.

- Semaphore operations now defined as

```
wait(S):
    S.count--;
    if (S.count < 0) {
        add this process to S.L;
        sleep;
    }

signal(S):
    S.count++;
    if (S.count <= 0) {
        remove a process P from S.L;
        wakeup(P);
    }
```

- Each primitive is atomic

Semaphore as a General Synchronization Tool

- Execute B in P_j only after A executed in P_i
- Use semaphore `count` initialized to 0
- Code:

```

P_i      P_j
⋮        ⋮
A        wait(flag)
signal(flag)  B
```

Semaphore Implementation of a Mutex

- Mutex is short for Mutual Exclusion
 - Can also be called a lock

```
semaphore mutex;
mutex.count = 1; /* initialise mutex */

wait(mutex); /* enter the critical region */

Blahblah();

signal(mutex); /* exit the critical region */
```

Notice that the initial count determines how many waits can progress before blocking and requiring a signal \Rightarrow mutex.count initialised as 1

Solving the producer-consumer problem with semaphores

```
#define N = 4

semaphore mutex = 1;

/* count empty slots */
semaphore empty = N;

/* count full slots */
semaphore full = 0;
```

Solving the producer-consumer problem with semaphores

```
prod() {
    while(TRUE) {
        item = produce();
        wait(empty);
        wait(mutex);
        insert_item();
        signal(mutex);
        signal(full);
    }
}

con() {
    while(TRUE) {
        wait(full);
        wait(mutex);
        remove_item();
        signal(mutex);
        signal(empty);
    }
}
```

Summarising

- Semaphores can be used to solve a variety of concurrency problems
- However, programming with them can be error-prone
 - E.g. must *signal* for every *wait* for mutexes
 - Too many, or too few signals or waits can have catastrophic results
