Dijkstra vs. Prim-Jarnik

Algorithm *DijkstraShortestPaths*(G, s)

```

 $Q \leftarrow$  new heap-based priority queue
for all  $v \in G.vertices()$ 
  if  $v = s$ 
     $setDistance(v, 0)$ 
  else
     $setDistance(v, \infty)$ 
     $setParent(v, \emptyset)$ 
   $l \leftarrow Q.insert(getDistance(v), v)$ 
   $setLocator(v, l)$ 
while  $\neg Q.isEmpty()$ 
   $u \leftarrow Q.removeMin()$ 
  for all  $e \in G.incidentEdges(u)$ 
     $z \leftarrow G.opposite(u, e)$ 
     $r \leftarrow getDistance(u) + weight(e)$ 
    if  $r < getDistance(z)$ 
       $setDistance(z, r)$ 
       $setParent(z, e)$ 
       $Q.replaceKey(getLocator(z), r)$ 

```

Algorithm *PrimJarnikMST*(G)

```

 $Q \leftarrow$  new heap-based priority queue
 $s \leftarrow$  a vertex of  $G$ 
for all  $v \in G.vertices()$ 
  if  $v = s$ 
     $setDistance(v, 0)$ 
  else
     $setDistance(v, \infty)$ 
     $setParent(v, \emptyset)$ 
   $l \leftarrow Q.insert(getDistance(v), v)$ 
   $setLocator(v, l)$ 
while  $\neg Q.isEmpty()$ 
   $u \leftarrow Q.removeMin()$ 
  for all  $e \in G.incidentEdges(u)$ 
     $z \leftarrow G.opposite(u, e)$ 
     $r \leftarrow weight(e)$ 
    if  $r < getDistance(z)$ 
       $setDistance(z, r)$ 
       $setParent(z, e)$ 
       $Q.replaceKey(getLocator(z), r)$ 

```

Kruskal's Algorithm (§ 12.7.1)

- ◆ A priority queue stores the edges outside the cloud
 - Key: weight
 - Element: edge
- ◆ At the end of the algorithm
 - We are left with one cloud that encompasses the MST
 - A tree T which is our MST

Algorithm *KruskalMST*(G)

```

for each vertex  $V$  in  $G$  do
  define a  $Cloud(v)$  of  $\leftarrow \{v\}$ 
let  $Q$  be a priority queue.
Insert all edges into  $Q$  using their
weights as the key
 $T \leftarrow \emptyset$ 
while  $T$  has fewer than  $n-1$  edges do
  edge  $e = T.removeMin()$ 
  Let  $u, v$  be the endpoints of  $e$ 
  if  $Cloud(v) \neq Cloud(u)$  then
    Add edge  $e$  to  $T$ 
    Merge  $Cloud(v)$  and  $Cloud(u)$ 
return  $T$ 

```

Data Structure for Kruskal Algorithm (§ 10.6.2)

- ◆ The algorithm maintains a forest of trees
- ◆ An edge is accepted if it connects distinct trees
- ◆ We need a data structure that maintains a **partition**, i.e., a collection of disjoint sets, with the operations:
 - **find**(u): return the set storing u
 - **union**(u,v): replace the sets storing u and v with their union

Representation of a Partition

- ◆ Each set is stored in a sequence
- ◆ Each element has a reference back to the set
 - operation **find**(u) takes $O(1)$ time, and returns the set of which u is a member.
 - in operation **union**(u,v), we move the elements of the smaller set to the sequence of the larger set and update their references
 - the time for operation **union**(u,v) is $\min(n_u, n_v)$, where n_u and n_v are the sizes of the sets storing u and v
- ◆ Whenever an element is processed, it goes into a set of size at least double, hence each element is processed at most $\log n$ times

Partition-Based Implementation

- ◆ A partition-based version of Kruskal's Algorithm performs cloud merges as unions and tests as finds.

Algorithm Kruskal(G):

Input: A weighted graph G .

Output: An MST T for G .

Let P be a partition of the vertices of G , where each vertex forms a separate set.

Let Q be a priority queue storing the edges of G , sorted by their weights

Let T be an initially-empty tree

while Q is not empty **do**

$(u,v) \leftarrow Q.removeMinElement()$

if $P.find(u) \neq P.find(v)$ **then**

 Add (u,v) to T

$P.union(u,v)$

return T

Running time:
 $O((n+m)\log n)$
