Specification and Simulation of Combinational Designs using VHDL

With thanks to Sudhakar Yalamanchili
Overview

1. Introduction to VHDL
   - Use in describing systems

2. Describing & modelling systems
   - Interface & behaviour
   - Signals, events, timing, concurrency
   - Use of discrete event simulation

3. Basic language constructs
   - Std_logic resolved type
   - Signal assignments
   - Delays
   - Modelling complex behaviour
   - Modelling structure

4. Use of VHDL to model and simulate sequential logic designs
1. Introduction to VHDL

- Use in describing systems
Systems may be described at multiple levels of abstraction.
The Digital System Design Process

- Requirements
  - Functional Design
    - Behavioral Simulation
  - Register Transfer Level Design
    - RTL Simulation
    - Validation
  - Logic Design
    - Logic Simulation
    - Verification
    - Fault Simulation
  - Circuit Design
    - Timing Simulation
    - Circuit Analysis
  - Physical Design
    - Design Rule Checking
- Description for Manufacture
Why Do We Describe Systems?

- Design Specification
  - unambiguous definition of components and interfaces in a large design
- Design Simulation
  - verify system/subsystem/chip performance prior to design implementation
- Design Synthesis
  - automated generation of a hardware design
Hardware Description Languages

- Design is structured around a hierarchy of representations
- HDLs can describe distinct aspects of a design at multiple levels of abstraction

[Gajski and Kuhn]
The VHDL Language

Very High Speed Integrated Circuit

Hardware

Description

Language

- Interoperability between design tools: standardized portable model of electronic systems
- Technology independent description
- Reuse of components described in VHDL
History of VHDL

- Designed by IBM, Texas Instruments, and Intermetrics as part of the DoD funded VHSIC program
- Standardized by the IEEE in 1987: IEEE 1076-1987
- Enhanced version of the language defined in 1993: IEEE 1076-1993
- Additional standardized packages provide definitions of data types and expressions of timing data
  - IEEE 1164 (data types)
  - IEEE 1076.3 (numeric)
  - IEEE 1076.4 (timing)
2. Describing & modelling systems

- Interface & behaviour
- Signals, events, timing, concurrency
- Use of discrete event simulation
Describing Systems

- System: “An assemblage of objects united by some form or regular interaction or dependence”
- What aspects of a digital system do we want to describe?
  - interface
  - behavior: functional and structural
Basic Language Concepts

• What aspects of a digital system do we want to describe?
  • interface: how do we connect to it
  • behavior: what does it do?
Describing the Interface: The Entity Construct

- The interface is a collection of *ports*
  - ports are a new programming object: *signal*
  - ports have a type, e.g., *bit*
  - ports have a mode: in, out, inout (bidirectional)

```vhdl
entity half_adder is
port ( a, b : in bit;
     sum, carry : out bit);
end half_adder;
```

entity half_adder is
port ( a, b : in bit;
     sum, carry : out bit);
end half_adder;
Example Entity Descriptions

entity ALU32 is
  port (A, B : in bit_vector (31 downto 0);
        C : out bit_vector (31 downto 0);
        Op : in bit_vector (5 downto 0);
        N, Z : out bit);
end ALU32;

entity D_ff is
  port (D, Q, Clk, R, S : in bit;
        Q, Qbar : out bit);
end D_ff;
Describing Behavior: The Architecture Construct

- Description of events on output signals in terms of events on input signals: the *signal assignment statement*
- Specification of propagation delays
- Type **bit** is not powerful enough for realistic simulation: use the IEEE 1164 value system

```vhdl
entity half_adder is
  port (a, b : in bit;
        sum, carry : out bit);
end half_adder;

architecture behavioral of half_adder is
begin
  sum <= (a xor b) after 5 ns;
  carry <= (a and b) after 5 ns;
end behavioral;
```
Behavioral Attributes of Digital Systems

- Digital systems are about *signals* and their *values*
- *Events, propagation delays, concurrency*
- Time ordered sequence of events produces a *waveform*
Behavioral Attributes of Digital Systems

- **Timing**: computation of events takes place at specific points in time
- Timing is an attribute of both synchronous and asynchronous systems

![Waveform and Logic Diagram](image)

**Waveform Diagram**

Simulation of Digital Systems

- Digital systems propagate events
- Discrete event simulations manage the generation and recording of events
Simulation Modeling

- VHDL programs describe the generation of events in digital systems
- Discrete event simulator manages event ordering and progression of time

HDL Description

Discrete event simulator

Altera, Viewlogic, Xilinx
Discrete Event Simulation: Half Adder Model

- Management of simulation time: ordering of events
- Two step model of the progression of time
Discrete Event Simulation Algorithm

repeat until event_list empty or preset simulation time expired:

1. Advance simulation time to that of the next event (earliest timestamp in the event list) and process all events (update all signals receiving values) at this time

2. Evaluate all components affected by signal updates and schedule any future events generated by inserting them into the event list
Modeling Digital Systems

- VHDL programs describe behavioral attributes of digital systems
  - events, propagation delays, concurrency
  - waveforms and timing
  - signal values
- Discrete event simulators mimic the operation of the system being described
  - two step model of time
    - assign values scheduled for signals at the current time
    - process affected components and schedule future signal values
  - ensures events are generated and processed in the correct order
  - a correct simulation generates *only and all* those events that would have been generated in the physical system
3. Basic language constructs

- Std_logic resolved type
- Signal assignments
- Delays
- Modelling complex behaviour
- Modelling structure
Describing Behavior: The Architecture Construct

- Description of events on output signals in terms of events on input signals: the signal assignment statement
- Specification of propagation delays
- Type `bit` is not powerful enough for realistic simulation: use the IEEE 1164 value system

```vhdl
entity half_adder is
  port (a, b : in bit;
       sum, carry :out bit);
end half_adder;

architecture behavioral of half_adder is
begin
  sum <= (a xor b) after 5 ns;
  carry <= (a and b) after 5 ns;
end behavior;
```
Behavioral Attributes of Digital Systems

- We associate logical values with the state of a signal

Signal Values: IEEE 1164 Value System

<table>

</tbody>
</table>
Implementation of Signals

- The structure of a signal assignment statement
  - \textit{signal} \texttt{<= (value expression after time expression)}
  - RHS is referred to as a \textit{waveform element}
- Every signal has associated with it a \textit{driver}

  \begin{itemize}
  \item holds the current and future values of the signal - a \textit{projected waveform}
  \item signal assignment statements modify the driver of a signal
  \item value of a signal is the value at the head of the driver
  \item note the hardware analogy
  \end{itemize}
Shared Signals

- How do we model the state of a wire?
- Rules for determining the signal value is captured in the resolution function
Resolution Function: std_logic & resolved()

- resolving values for std_logic types

- Pairwise resolution of signal values from multiple drivers
- Resolution operation must be associative
Example Entity Descriptions: IEEE 1164

entity ALU32 is
port(  A, B: in std_logic_vector (31 downto 0);
       C: out std_logic_vector (31 downto 0);
       Op: in std_logic_vector (5 downto 0);
       N, Z: out std_logic);
end ALU32;

entity D_ff is
port(  D, Q, Clk, R, S: in std_ulogic;
       Q, Qbar: out std_ulogic);
end D_ff;
library IEEE;
use IEEE.std_logic_1164.all;

entity half_adder is
port ( a, b : in std_logic;
       sum, carry :out std_logic);
end half_adder;

architecture behavioral of half_adder is
begin
sum <= (a xor b) after 5 ns;
carry <= (a and b) after 5 ns;
end behavioral;

- Use of the IEEE 1164 value system simply requires inclusion of the library and package declarations statements
Design Units

- An entity may have multiple architectures
- Separation of interface from implementation
library IEEE;
use IEEE.std_logic_1164.all;
entity full_adder is
port (in1, in2, c_in: in std_logic;
     sum, c_out: out std_logic);
end full_adder;

architecture dataflow of full_adder is
signal s1, s2, s3 : std_logic;
constant gate_delay: Time:= 5 ns;
begin
L1: s1 <= (In1 xor In2) after gate_delay;
L2: s2 <= (c_in and s1) after gate_delay;
L3: s3 <= (In1 and In2) after gate_delay;
L4: sum <= (s1 xor c_in) after gate_delay;
L5: c_out <= (s2 or s3) after gate_delay;
end dataflow;
Simple Signal Assignment Statement

- The *constant* programming object
  - values cannot be changed
- Use of signals in the architecture
  - internal signals used to connect components
- A statement is executed when a signal in the RHS has value assigned to it
  - 1-1 correspondence between signal assignment statements and signals in the circuit
  - order of statement execution follows propagation of events in the circuit
  - textual order *does not* imply execution order
  - trace the statement execution order when In1 changes value
Understanding Delays

- Inertial delay model
- Transport delay model
- Delta delay model
Understanding Delays

- Inertial delay
  - default delay model
  - suitable for modeling delays through devices such as gates
- Transport Delay
  - to model delays through devices with very small inertia, e.g., wires
  - all input events are propagated to output signals
- Delta delay
  - what about models where no propagation delays are specified?
  - infinitesimally small delay is automatically inserted by the simulator to preserve correct ordering of events
Transport Delays: Example

architecture transport_delay of half_adder is
signal s1, s2: std_logic := ‘0’;
begin
  s1 <= (a xor b) after 2 ns;
s2 <= (a and b) after 2 ns;
  sum <= transport s1 after 4 ns;
  carry <= transport s2 after 4 ns;
end transport_delay;
Delta Delays: Example

```vhdl
library IEEE;
use IEEE.std_logic_1164.all;
entity combinational is
  port (In1, In2: in std_logic;
        z : out std_logic);
end combinational;

architecture behavior of combinational is
  signal s1, s2, s3, s4: std_logic:=
  begin
    s1 <= not In1;
    s2 <= not In2;
    s3 <= not (s1 and In2);
    s4 <= not (s2 and In1);
    z <= not (s3 and s4);
  end behavior;
```
Delta Delays: Example

Delta events

Conditional Signal Assignment

library IEEE;
use IEEE.std_logic_1164.all;
entity mux4 is
port (   In0, In1, In2, In3 : in std_logic_vector (7 downto 0);
    Sel: in std_logic_vector(1 downto 0);
    Z : out std_logic_vector (7 downto 0));
end mux4;

architecture behavioral of mux4 is
begin
Z <= In0 after 5 ns when Sel = “00” else
    In1 after 5 ns when Sel = “01” else
    In2 after 5 ns when Sel = “10” else
    In3 after 5 ns when Sel = “11” else
    “00000000” after 5 ns;
end behavioral;

- First true conditional determines the output value
Selected Signal Assignment Statement

library IEEE;
use IEEE.std_logic_1164.all;
entity mux4 is
port (  In0, In1, In2, In3 : in std_logic_vector (7 downto 0);
       Sel: in std_logic_vector(1 downto 0);
       Z : out std_logic_vector (7 downto 0));
end mux4;

architecture behavioral-2 of mux4 is
begin
with Sel select
Z <= (In0 after 5 ns) when "00",
     (In1 after 5 ns) when "01",
     (In2 after 5 ns) when "10",
     (In3 after 5 ns) when "11",
     (In3 after 5 ns) when others;
end behavioral;

• The “when others” clause can be used to ensure that all options are covered

All options must be covered and only one must be true!
Modeling Complex Behavior

- Concurrent signal assignment statements can easily capture the gate level behavior of digital systems
- Higher level digital components have more complex behaviors
  - input/output behavior not easily captured by concurrent signal assignment statements
  - models utilize state information
  - incorporate data structures
- We need more powerful constructs
library IEEE;
use IEEE.std_logic_1164.all;
entity mux4 is
port ( In0, In1, In2, In3 : in std_logic_vector (7 downto 0);
       Sel: in std_logic_vector(1 downto 0);
       Z : out std_logic_vector (7 downto 0));
end mux4;

architecture behavioral-3 of mux4 is
begin
process (Sel, In0, In1, In2, In3)
variable Zout: std_logic;
begin
  if (Sel = “00”) then Zout:= In0;
  elsif (Sel = “01”) then Zout:= In1;
  elsif (Sel = “10”) then Zout:= In2;
  else Zout:= In3;
  end if;
  Z <= Zout;
end process;
end behavioral;
The Process Construct

- Statements in a process are executed sequentially
- A process body is structured much like conventional C or Pascal programs
  - declaration and use of variables
  - if-then, if-then-else, case, loop and while constructs
  - process can contain signal assignment statements
- A process executes concurrently with other concurrent signal assignment statements
- A process takes 0 simulation time to execute and may schedule events in the future: we can think of a process as a complex signal assignment statement!
Concurrent Processes: Full Adder

- Each of the components of the full adder can be modeled using a process
- Processes execute concurrently
- Processes communicate via signals
Concurrent Processes: Full Adder

library IEEE;
use IEEE.std_logic_1164.all;

entity full_adder is
port (In1, c_in, In2 : in std_logic;
      sum, c_out : out std_logic);
end full_adder;

architecture behavioral of full_adder is
signal s1, s2, s3: std_logic;
constant delay : Time:= 5 ns;
begin
HA1: process (In1, In2)
begin
s1 <= (In1 xor In2) after delay;
s3 <= (In1 and In2) after delay;
end process HA1;

HA2: process(s1,c_in)
begin
sum <= (s1 xor c_in) after delay;
s2 <= (s1 and c_in) after delay;
end process HA2;

OR1: process (s2, s3) -- process describing the two-input OR gate
begin
c_out <= (s2 or s3) after delay;
end process OR1;
end behavioral;
Concurrent Processes: Half Adder

library IEEE;
use IEEE.std_logic_1164.all;

dentity half_adder is
port (a, b: in std_logic;
sum, carry: out std_logic);
end half_adder;

architecture behavior of half_adder is
begin
sum_proc: process(a,b)
begin
if (a = b) then
sum <= '0' after 5 ns;
else
sum <= (a or b) after 5 ns;
end if;
end process;

carry_proc: process (a,b)
begin
case a is
when '0' =>
carry <= a after 5 ns;
when '1' =>
carry <= b after 5 ns;
when others =>
carry <= 'X' after 5 ns;
end case;
end process carry_proc;
end behavior;
library IEEE;
use IEEE.std_logic_1164.all;
entity dff is
port (D, Clk : in std_logic;
     Q, Qbar : out std_logic);
end dff;

architecture behavioral of dff is
begin
output: process
begin
wait until (Clk’event and Clk = ‘1’); -- wait for edge
Q <= D after 5 ns;
Qbar <= not D after 5 ns;
end process output;
end behavioral;

- wait for <time expression>, wait on <signal>, wait until <boolean expression>
The Wait Statement: Waveform Generation

library IEEE;
use IEEE.std_logic_1164.all;
entity two_phase is
port (phi1, phi2, reset : out std_logic);
end two_phase;

architecture behavioral of two_phase is
begin
rproc: reset <= '1', '0' after 10 ns;
clock_process: process begin
phi1 <= '1', '0' after 10 ns;
phi2 <= '0', '1' after 12 ns, '0' after 18 ns;
wait for 20 ns;
end process clock_process;
end behavioral;

Events specified by the reset and clock processes.
The Wait Statement

- A process can have multiple wait statements
- A process cannot have both a wait statement and a sensitivity list (it should have one or the other)
Modeling Structure

- Structural models describe a digital system as an interconnection of components
- Descriptions of the components must be available as structural or behavioral models
Modeling Structure

- Define the components used in the design
- Describe the interconnection of these components
Modeling Structure

architecture structural of full_adder is
component half_adder                 -- the declaration
port (a, b: in std_logic;
      sum, carry: out std_logic);
end component;

component or_2
  port (a, b: in std_logic;
       c: out std_logic);
end component;

signal s1, s2, s3: std_logic;
begin
  H1: half_adder port map (a => In1, b => In2, sum=>s1, carry=>s3);
  H2: half_adder port map (a => s1, b => c_in, sum=>sum,
                            carry=>s2);
  O1: or_2 port map (a => s2, b => s3, c => c_out);
end structural;

- Entity/architecture for half_adder and or_2 must exist
Hierarchy and Abstraction

architecture structural of half_adder is
component xor2
  port (a, b : in std_logic;
       c : out std_logic);
end component;
component and2
  port (a, b : in std_logic;
       c : out std_logic);
end component;
begin
EX1: xor2 port map (a => a, b => b, c => sum);
AND1: and2 port map (a => a, b => b, c => carry);
end structural;

- Structural descriptions can be nested
- The half adder may itself be a structural model
Hierarchy and Abstraction

- Nested structural descriptions to produce hierarchical models
- The hierarchy is flattened prior to simulation
- Behavioral models of components at the bottom level must exist
Generics

library IEEE;
use IEEE.std_logic_1164.all;

entity xor2 is
  generic (gate_delay: Time:= 2 ns);
  port(In1, In2: in std_logic;
       z: out std_logic);
end xor2;

architecture behavioral of xor2 is
begin
  z <= (In1 xor In2) after gate_delay;
end behavioral;

- Enables the construction of parameterized models
Generics in Hierarchical Models

```vhdl
architecture generic_delay of half_adder is
component xor2
generic (gate_delay: Time);
port (a, b : in std_logic;
      c : out std_logic);
end component;

component and2
generic (gate_delay: Time);
port (a, b : in std_logic;
      c : out std_logic);
end component;

begin
EX1: xor2 generic map (gate_delay => 6 ns)
      port map(a => a, b => b, c => sum);
A1: and2 generic map (gate_delay => 3 ns)
      port map(a => a, b => b, c => carry);
end generic_delay;
```

- Parameter values are passed through the hierarchy
Example: Full Adder

```
<table>
<thead>
<tr>
<th>HA</th>
<th>HA</th>
</tr>
</thead>
<tbody>
<tr>
<td>H1</td>
<td>H2</td>
</tr>
</tbody>
</table>

In1 | In2 | c_in | s1 | s2 | s3 | sum | c_out |

---

```

```
full_adder.vhd

-- top level

half_adder.vhd

-- bottom level

or2.vhd

and2.vhd

xor2.vhd

---
Example: Full Adder

```
H1: half_adder generic map (gate_delay => 6 ns)
    port map(a => In1, b => In2, sum => s1, carry=>s2);
H2: half_adder ...
```

*from full_adder.vhd*

```
EX1: xor2 generic map
    (gate_delay=>gate_delay,
     ...
A1: and2 generic map
    (gate_delay=>gate_delay,
     ...
```

*half_adder.vhd*

```
entity and2 is
generic (gate_delay : Time:= 2 ns);
    ...
```

*xor2.vhd*

```
entity xor2 is
generic (gate_delay : Time := 2 ns);
    ...
```

*and2.vhd*
Precedence of Generic Declarations

architecture generic_delay2 of half_adder is
component xor2
generic (gate_delay: Time);
port(a, b : in std_logic;
    c : out std_logic);
end component;

component and2
generic (gate_delay: Time:= 6 ns);
port(a, b : in std_logic;
    c : out std_logic);
end component;

begin
EX1: xor2 generic map (gate_delay => gate_delay)
    port map(a => a, b => b, c => sum);
A1: and2 generic map (gate_delay => 4 ns)
    port map(a => a, b => b, c => carry);
end generic_delay2;

- Generic map takes precedence over the component declaration
Further reading

• VHDL Starter’s Guide, Sudhakar Yalamanchili
• Check the VHDL references link from the course web page
• Look at the on-line documentation available with ISE – there is a huge VHDL manual
• There are many on-line VHDL tutorials available
Homework

1. Download and install WebPack and ModelSim as described on the VHDL references course web page,

OR

Access the ISE Project Manager from a vmware enabled school Linux workstation;

AND

2. Familiarize yourself with the design environment by completing the Tutorial and testing the designs we have discussed in lectures.
