First-Come First-Served (FCFS)

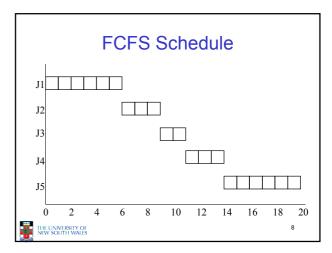

Algorithm

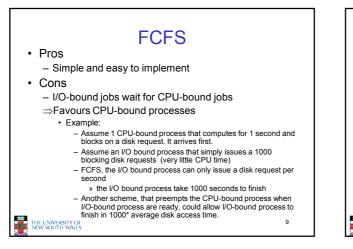

- Each job is placed in single queue, the first job in the queue is selected, and allowed to run as long as it wants.
- If the job blocks, the next job in the queue is selected to run
- When a blocked jobs becomes ready, it is placed at the end of the queue

6

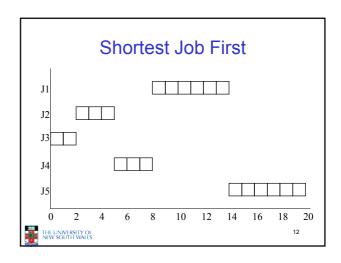

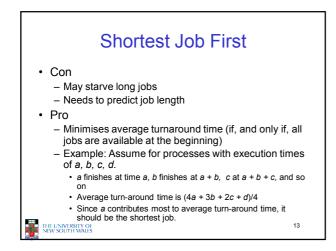

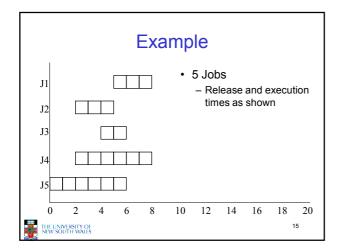

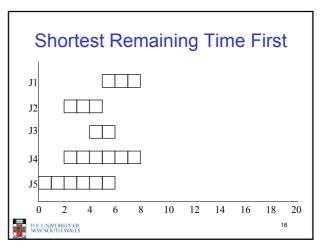

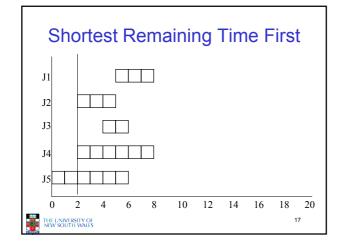

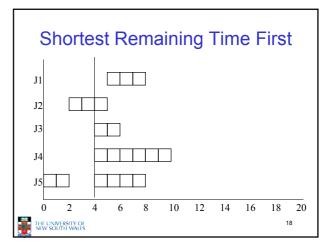

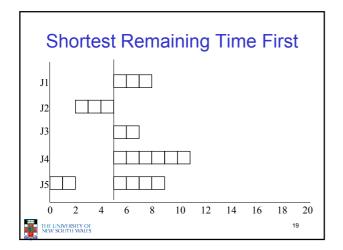

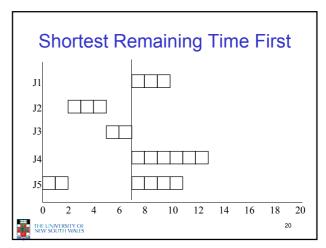

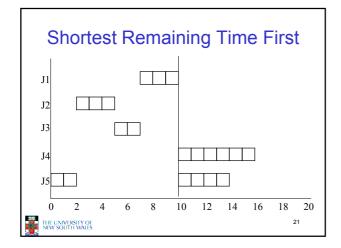

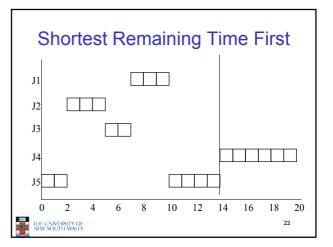

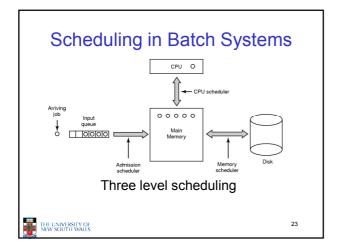

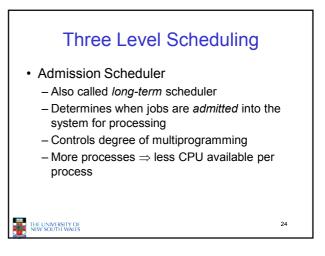

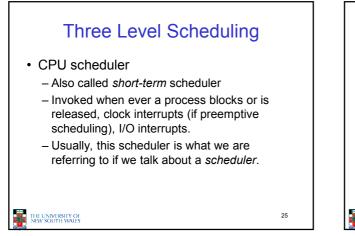

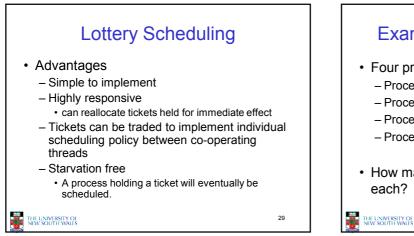

Three Level Scheduling

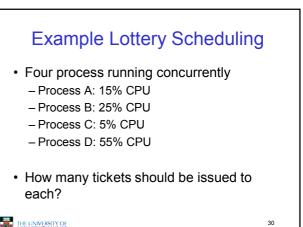

- · Memory Scheduler
 - Also called medium-term scheduler
 - Adjusts the degree of multiprogramming via suspending processes and swapping them out

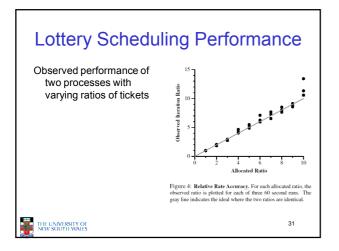

26

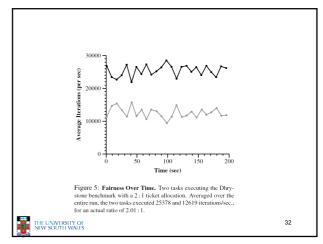

THE UNIVERSITY OF NEW SOUTH WALES

Some Issues with Priorities Lottery Scheduling · Require adaption over time to avoid starvation · Each process is issued with "lottery (not considering hard real-time which relies on tickets" which represent the right to strict priorities). use/consume a resource · Adaption is: - Example: CPU time - usually ad-hoc, · hence behaviour not thoroughly understood, and Access to a resource is via "drawing" a unpredictable lottery winner. Gradual, hence unresponsive · Difficult to guarantee a desired share of the CPU - The more tickets a process possesses, the · No way for applications to trade CPU time higher chance the process has of winning. 27 28 THE UNIVERSITY OF NEW SOUTH WALES THE UNIVERSITY OF NEW SOUTH WALES

Fair-Share Scheduling · So far we have treated processes as individuals Assume two users - One user has 1 process - Second user has 9 processes The second user gets 90% of the CPU • • Some schedulers consider the owner of the process in determining which process to schedule $-\,$ E.g., for the above example we could schedule the first user's process 9 times more often than the second user's processes • Many possibilities exist to determine a fair schedule - E.g. Appropriate allocation of tickets in lottery scheduler THE UNIVERSITY OF NEW SOUTH WALES 33
