

TLB Recap

- Fast associative cache of page table entries
 - Contains a subset of the page table
 - What happens if required entry for translation is not present (a *TLB miss*)?

2

TLB Recap

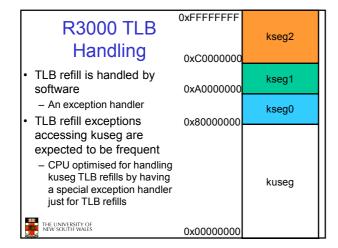

- TLB may or may not be under OS control
 - Hardware-loaded TLB
 - On miss, hardware performs PT lookup and reloads TLB
 - Example: Pentium
 - Software-loaded TLB
 - On miss, hardware generates a TLB miss exception, and exception handler reloads TLB
 - Example: MIPS

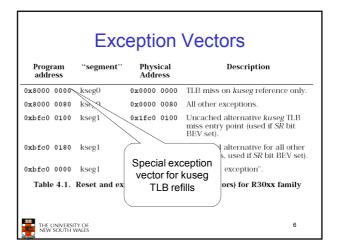

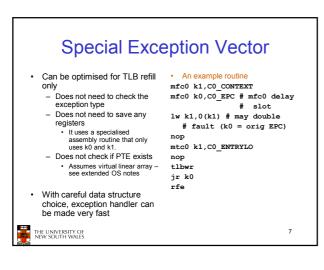

Aside: even if filled by software

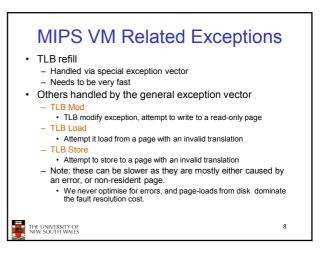

· TLB still a hardware translator

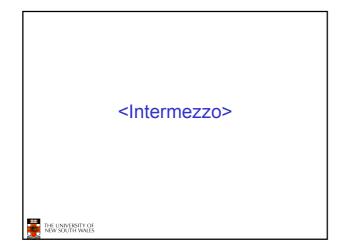

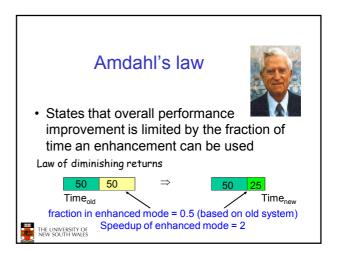

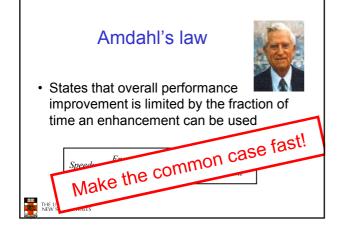

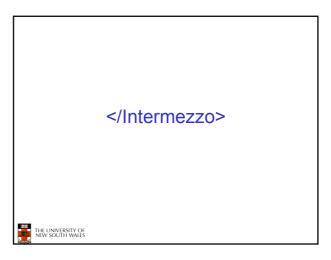

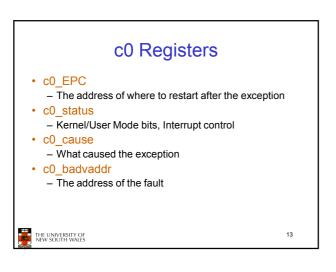

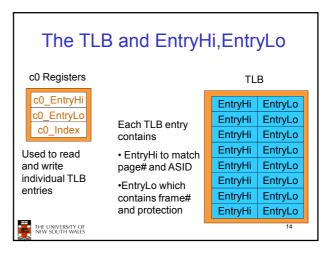

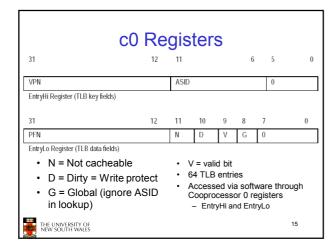

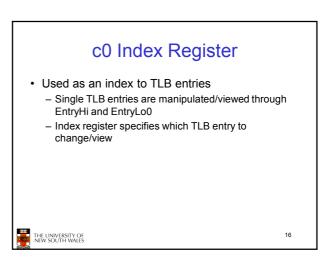

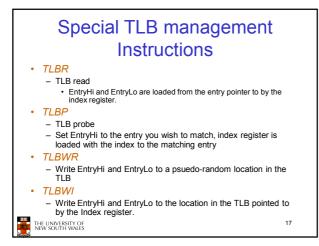

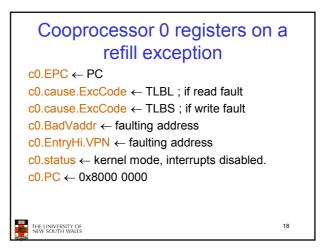

Outline of TLB miss handling

- · Software does:
 - Look up PTE corresponding to the faulting address
 - If found:
 - load c0_EntryLo with translation
 - load TLB using TLBWR instructions
 - return from exception
 - Else, page fault
- The TLB entry (i.e. c0_EntryLo) can be:
 - created on the fly, or
 - stored completely in the right format in page table
 - more efficient

10

OS/161 Refill Handler

- After switch to kernel stack, it simply calls the common exception handler
 - Stacks all registers
 - Can (and does) call 'C' code
 - Unoptimised
 - Goal is ease of kernel programming, not efficiency
- · Does not have a page table
 - It uses the 64 TLB entries and then panics when it runs out.
 - Only support 256K user-level address space

20

Demand Paging/Segmentation

21

Demand Paging/Segmentation

- With VM, only parts of the program image need to be resident in memory for execution.
- Can transfer presently unused pages/segments to disk
- Reload non-resident pages/segment on demand.
 - Reload is triggered by a page or segment fault
 - Faulting process is blocked and another scheduled
 - When page/segment is resident, faulting process is restarted
 - May require freeing up memory first
 - Replace current resident page/segment
 - How determine replacement "victim"?
 - If victim is unmodified ("clean") can simply discard it
 - · This is reason for maintaining a "dirty" bit in the PT

22

- · Why does demand paging/segmentation work?
 - Program executes at full speed only when accessing the resident set.
 - TLB misses introduce delays of several microseconds
 - Page/segment faults introduce delays of several milliseconds
 - Why do it?
- Answer
 - Less physical memory required per process
 - · Can fit more processes in memory
 - Improved chance of finding a runnable one
 - Principle of locality

23

Principle of Locality

- An important observation comes from empirical studies of the properties of programs.
 - Programs tend to reuse data and instructions they have used recently.
 - 90/10 rule
 - "A program spends 90% of its time in 10% of its code"
- We can exploit this <u>locality of references</u>
- An implication of locality is that we can reasonably predict what <u>instructions</u> and <u>data</u> a program will use in the near future based on its accesses in the recent past.

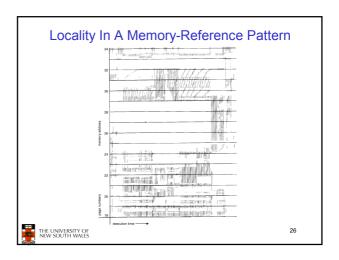

Two different types of locality have been observed:

- Temporal locality: states that recently accessed items are likely to be accessed in the near future.
- Spatial locality: says that items whose addresses are near one another tend to be referenced close together in time.

25

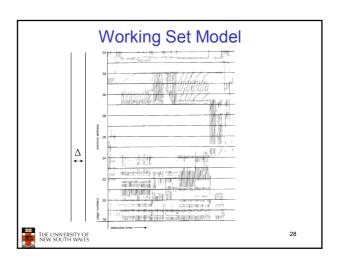

Working Set

- The pages/segments required by an application in a time window (Δ)is called its memory working set.
- · Working set is an approximation of a programs' locality
 - $-\,$ if Δ too small will not encompass entire locality.
 - if Δ too large will encompass several localities.
 - if Δ = ∞ \Rightarrow will encompass entire program.
 - $-\ \Delta \mbox{'s}$ size is an application specific tradeoff
- System should keep resident at least a process's working set
- Process executes while it remains in its working set
- Working set tends to change gradually
 - Get only a few page/segment faults during a time window
 - Possible to make intelligent guesses about which pieces will be needed in the future
 - May be able to pre-fetch page/segments

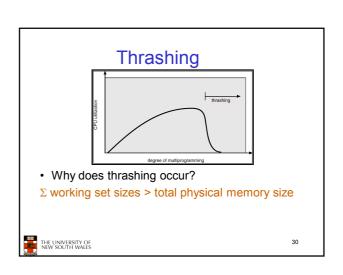

27

Thrashing

- CPU utilisation tends to increase with the degree of multiprogramming
 - number of processes in system
- Higher degrees of multiprogramming less memory available per process
- Some process's working sets may no longer fit in RAM
 - Implies an increasing page fault rate
- Eventually many processes have insufficient memory
 - Can't always find a runnable process
 - Decreasing CPU utilisation
 - System become I/O limited
- This is called thrashing.

Recovery From Thrashing

- In the presence of increasing page fault frequency and decreasing CPU utilisation
 - Suspend a few processes to reduce degree of multiprogramming
 - Resident pages of suspended processes will migrate to backing store
 - More physical memory becomes available
 - Less faults, faster progress for runnable processes
 - Resume suspended processes later when memory pressure eases

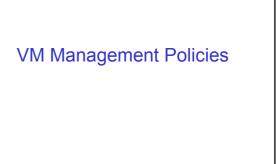

31

Quiz

- · how does an IPT work?
 - what is good about it?
 - what is bad about it?
- what is the TLB?
 - what happens on a context switch?
- · what is a working set?
- · what is thrashing?

What is the difference? /* reset array */ int array[10000][10000]; int i,j; for (i = 0; i < 10000; i++) { for (j = 0; j < 10000; j ++) { array[i][j] = 0; /* array[j][i] = 0 */ } }</pre>

VM Management Policies

- Operation and performance of VM system is dependent on a number of policies:
 - Page table format (my be dictated by hardware)
 - Multi-level
 - Hashed
 - Page size (may be dictated by hardware)
 - Fetch Policy
 - Replacement policy
 - Resident set size
 - · Minimum allocation
 - Local versus global allocation
 - Page cleaning policy
 - Degree of multiprogramming

35

Page Size

Increasing page size

THE UNIVERSITY OF NEW SOUTH WALES

- × Increases internal fragmentation
 - reduces adaptability to working set size
- ✓ Decreases number of pages
- Reduces size of page tables
- ✓ Increases TLB coverage
 - Reduces number of TLB misses
- Increases page fault latency
 - Need to read more from disk before restarting process
- ✓ Increases swapping I/O throughput
 - Small I/O are dominated by seek/rotation delays
- Optimal page size is a (work-load dependent) trade-off.

Atlas	512 words (48-bit)
Honeywell/Multics	1K words (36-bit)
IBM 370/XA	4K bytes
DEC VAX	512 bytes
IBM AS/400	512 bytes
Intel Pentium	4K and 4M bytes
ARM	4K and 64K bytes
MIPS R4000	4k – 16M bytes in powers of 4
DEC Alpha	8K - 4M bytes in powers of 8
UltraSPARC	8K – 4M bytes in powers of 8
PowerPC	4K bytes + "blocks"
Intel IA-64	4K – 256M bytes in powers of 4

37

Page Size

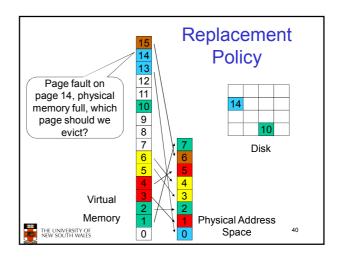

- · Multiple page sizes provide flexibility to optimise the use of the TLB
- Example:
 - Large page sizes can be use for code
 - Small page size for thread stacks
- · Most operating systems support only a single page size
 - Dealing with multiple page sizes is hard!

Fetch Policy

- Determines when a page should be brought into memory
 - Demand paging only loads pages in response to page faults
 - Many page faults when a process first starts
 - Pre-paging brings in more pages than needed at the moment
 - Improves I/O performance by reading in larger chunks
 - Pre-fetch when disk is idle
 - Wastes I/O bandwidth if pre-fetched pages aren't used
 - Especially bad if we eject pages in working set in order to pre-fetch unused pages.
 Hard to get right in practice.

Replacement Policy

- · Which page is chosen to be tossed out?
 - Page removed should be the page least likely to be references in the near future
 - Most policies attempt to predict the future behaviour on the basis of past behaviour
- Constraint: locked frames
 - Kernel code
 - Main kernel data structure
 - I/O buffers
 - Performance-critical user-pages (e.g. for DBMS)
- Frame table has a lock bit

Optimal Replacement policy

- · Toss the page that won't be used for the longest
- · Impossible to implement
- Only good as a theoretic reference point:
 - The closer a practical algorithm gets to optimal, the better
- · Example:
 - Reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5
 - Four frames
 - How many page faults?

FIFO Replacement Policy

- · First-in, first-out: Toss the oldest page
 - Easy to implement
 - Age of a page is isn't necessarily related to usage
- · Example:
 - Reference string: 1,2,3,4,1,2,5,1,2,3,4,5
 - Four frames
 - How many page faults?
 - Three frames?

43

FIFO Replacement Policy

- · First-in, first-out: Toss the oldest page
 - Easy to implement
 - Age of a page is isn't necessarily related to usage
- · Example:
 - Reference string: 1,2,3,4,1,2,5,1,2,3,4,5
 - Four frames
 - How many page faults?
 - Three frames?

44

Belady's Anomaly

 For FIFO, more frames does not imply fewer page faults

Least Recently Used (LRU)

- · Toss the least recently used page
 - Assumes that page that has not been referenced for a long time is unlikely to be referenced in the near future
 - Will work if locality holds
 - Implementation requires a time stamp to be kept for each page, updated on every reference
 - Impossible to implement efficiently
 - Most practical algorithms are approximations of LRU

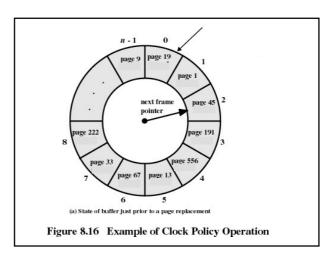

46

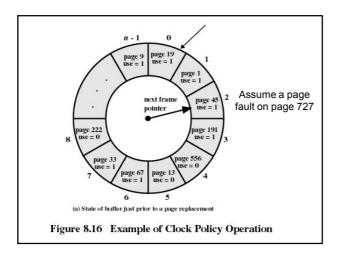

Clock Page Replacement

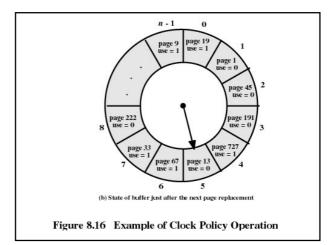

- · Clock policy, also called second chance
 - Employs a usage or reference bit in the frame table.
 - Set to one when page is used
 - While scanning for a victim, reset all the reference bits
 - Toss the first page with a zero reference bit.

47

Issue

- · How do we know when a page is referenced?
- · Use the valid bit in the PTE:
 - When a page is mapped (valid bit set), set the reference bit
 - When resetting the reference bit, invalidate the PTE entry
 - On page fault
 - Turn on valid bit in PTE
 - Turn on reference bit
- · We thus simulate a reference bit in software

51

Performance

- It terms of selecting the most appropriate replacement, they rank as follows
 - 1. Optimal
 - 2. LRU
 - 3. Clock
- 4. FIFO
- Note there are other algorithms (Working Set, WSclock, Ageing, NFU, NRU)
 - We don't expect you to know them in this course

5

Resident Set Size

- · How many frames should each process have?
 - Fixed Allocation
 - Gives a process a fixed number of pages within which to execute.
 - When a page fault occurs, one of the pages of that process must be replaced.
 - · Achieving high utilisation is an issue.
 - Some processes have high fault rate while others don't use their allocation
 - Variable Allocation
 - Number of pages allocated to a process varies over the lifetime of the process

53

Variable Allocation, Global Scope

- Easiest to implement
- Adopted by many operating systems
- Operating system keeps global list of free frames
- Free frame is added to resident set of process when a page fault occurs
- If no free frame, replaces one from any process
- Pro/Cons
 - Automatic balancing across system
 - Does not provide guarantees for important activities

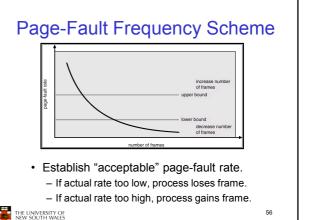

Variable Allocation, Local Scope

- Allocate number of page frames to a new process based on
 - Application type
 - Program request
 - Other criteria (priority)
- When a page fault occurs, select a page from among the resident set of the process that suffers the page fault
- · Re-evaluate allocation from time to time!

55

Cleaning Policy

- Observation
- Clean pages are much cheaper to replace than dirty pages
- Demand cleaning
 - A page is written out only when it has been selected for replacement
 - High latency between the decision to replace and availability of free frame.
- Precleaning
 - Pages are written out in batches (in the background, the pagedaemon)
 - Increases likelihood of replacing clean frames
 - Overlap I/O with current activity

57

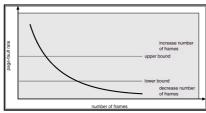

Load Control (Degree of multiprogramming)

- Determines the number of runnable processes
- · Controlled by:
 - Admission control
 - Only let new process's threads enter *ready* state if enough memory is available
 - Suspension:
 - Move all threads of some process into a special suspended state
 - Swap complete process image of suspended process to disk
- Trade-off
 - Too many processes will lead to thrashing
 - Too few will lead to idle CPU

58

Load Control Considerations

· Can use page fault frequency.
