

Issues

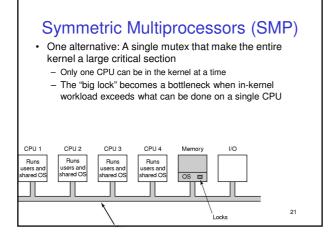

- Each processor has its own scheduling queue
 We can have one processor overloaded, and the rest idle
- Each processor has its own memory partition
 - We can a one processor thrashing, and the others with free memory
 No way to move free memory from one OS to another
- Consistency is an issue with independent disk buffer caches and potentially shared files

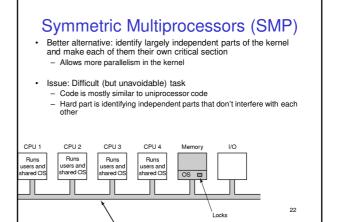

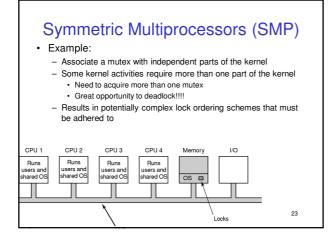

Symmetric Multiprocessors (SMP)

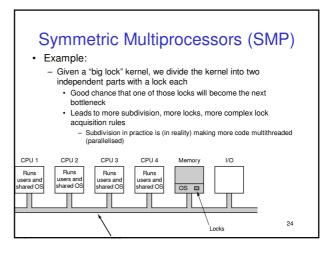

- OS kernel run on all processors
 Load and resource are balance between all processors
 including kernel execution
- Issue: Real concurrency in the kernel
- Need carefully applied synchronisation primitives to avoid disaster

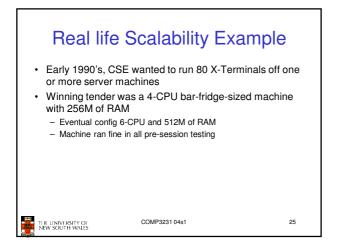

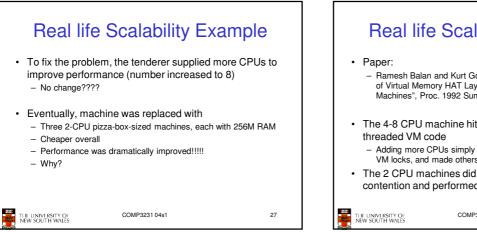

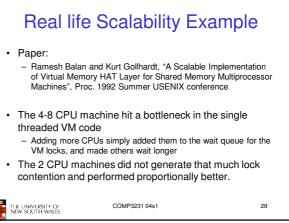

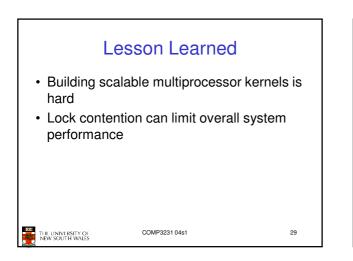

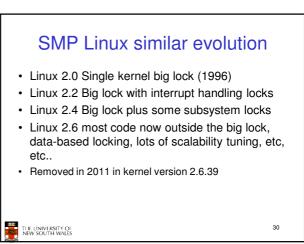

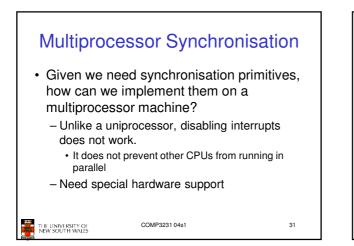

Real life Scalability Example • Students + assignment deadline = machine unusable

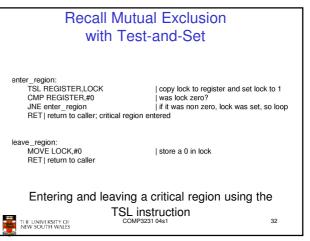

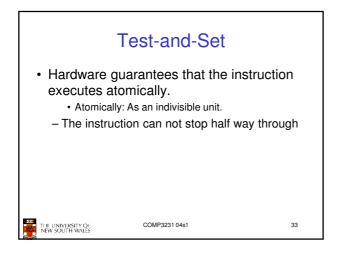

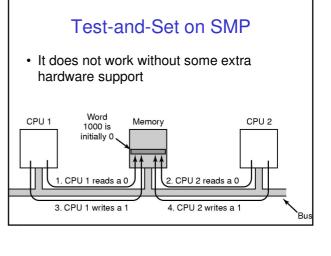

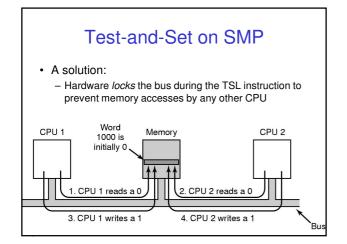

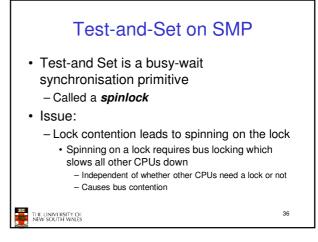

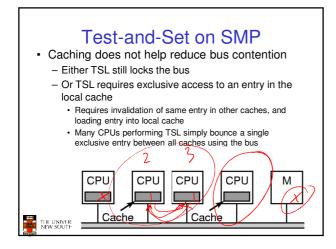

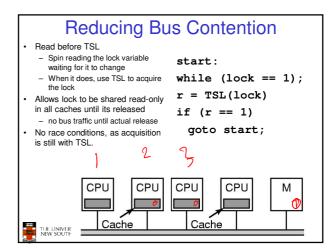

Thomas Anderson, "The Performance of Spin Lock Alternatives for Shared-Memory Multiprocessors", *IEEE Transactions on Parallel and Distributed Systems*, Vol 1, No. 1, 1990

Compares Simple Spinlocks

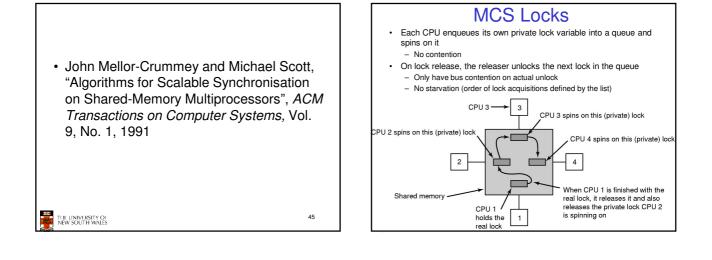

• Test and Set
void lock (volatile lock_t *1) {
 while (test_and_set(1)) ;
}

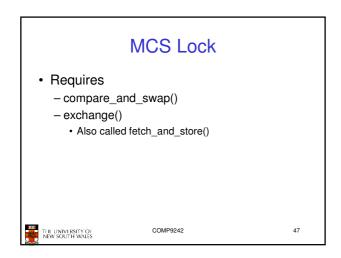

• Read before Test and Set
void lock (volatile lock_t *1) {
 while (*1 == BUSY || test_and_set(1)) ;
}

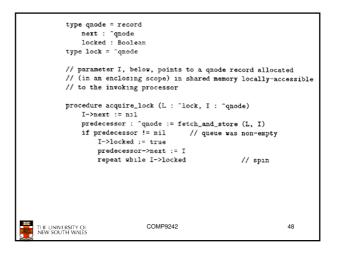

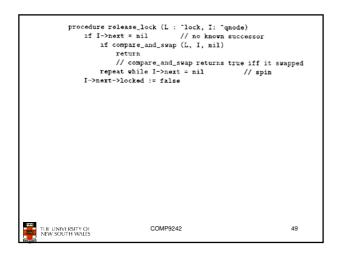

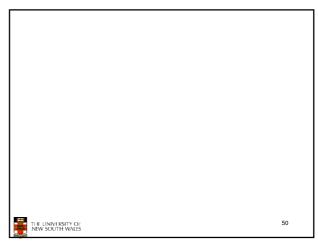

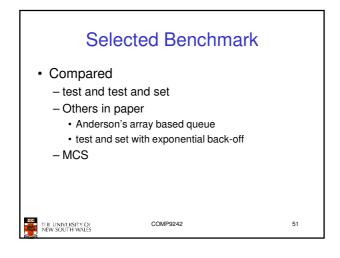

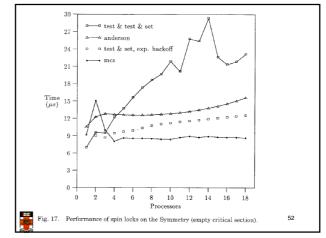

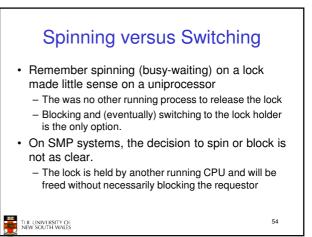

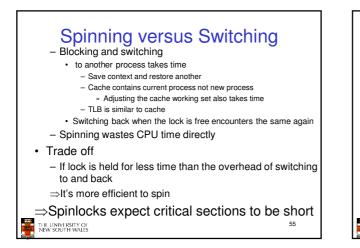

Preemption and Spinlocks

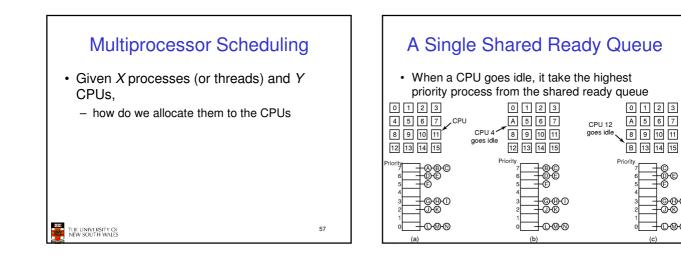

Critical sections synchronised via spinlocks are expected to be short

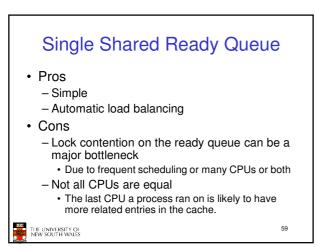

- Avoid other CPUs wasting cycles spinning

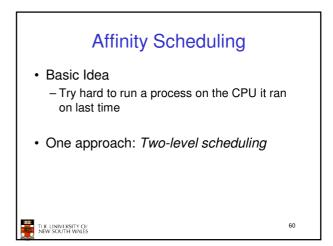

- What happens if the spinlock holder is preempted at end of holder's timeslice
 - Mutual exclusion is still guaranteed
 - Other CPUs will spin until the holder is scheduled again!!!!!
- ⇒ Spinlock implementations disable interrupts in addition to acquiring locks to avoid lock-holder preemption

Two-level Scheduling

• Pros

- No lock contention on per-CPU ready queues in the (hopefully) common case
- Load balancing to avoid idle queues
- Automatic affinity to a single CPU for more cache friendly behaviour
