

COMP9242
Advanced Operating Systems
S2/2011 Week 6:
Performance Evaluation

NICTA Funding and Supporting Members and Partners

Overview

- Performance
- Benchmarking
- Profiling
- Performance analysis

Purpose of Performance Evaluation

Research:

- Establish performance advantages/disadvantages of approach
 - may investigate performance limits
 - should investigate tradeoffs

Development:

- Ensure product meets performance objectives
 - new features must not unduly impact performance of existing features
 - quality assurance

Purchasing:

- Ensure proposed solution meets requirements
 - avoid buying snake oil
- Identify best of several competing products

Different objectives may require different approaches

Benchmarking in Research

- Generally one of two objectives:
 - Show new approach improves performance
 - Show otherwise attractive approach does not undermine performance
- Requirement: objectivity/fairness
 - Selection of baseline
 - Inclusion of relevant alternatives
 - Fair evaluation of alternatives
- Requirement: analysis/explanation of results
 - Model of system, incorporating relevant parameters
 - Hypothesis of behaviour
 - Results must support hypothesis

What Performance?

- Cold cache vs hot cache
 - hot-cache figures are easy to produce and reproduce
 - but are they meaningful?
- Best case vs average case vs worst case
 - best-case figures are nice — but are they useful?
 - average case — what defines the “average”?
 - expected case — what defines it?
 - worst case — is it really “worst” or just bad? Does it matter?
- What does “performance” mean?
 - is there an absolute measure?
 - can it be compared? With what?
 - *Benchmarking*

Note: Always analyse performance before optimising!

- Ensure that you focus on the bottlenecks, they may be non-obvious!

Overview

- Performance
- **Benchmarking**
- Profiling
- Performance analysis

Lies, Damned Lies, Benchmarks

- Micro- vs macro-benchmarks
- Synthetic vs “real-world”
- Benchmark suites, use of subsets
- Completeness of results
- Significance of results
- Baseline for comparison
- Benchmarking ethics
- What is good — analysing the results

Micro- vs Macro-Benchmarks

- Macro-benchmarks
 - Use realistic workloads
 - Measure real-life system performance (hopefully)
- Micro-benchmarks
 - Exercise particular operation, e.g. single system call
 - Good for analysing performance / narrowing down performance bottlenecks
 - critical operation is slower than expected
 - critical operation performed more frequently than expected
 - operation is unexpectedly critical (because it's too slow)

Micro- vs Macro-Benchmarks

Benchmarking Crime: Micro-benchmarks only:

- Pretend micro-benchmarks represent overall system performance
- Real performance can in general not be assessed with micro-benchmarks
- Exceptions:
 - Focus is on improving particular operation known to be critical
 - There is an established base line

Note: My macro-benchmark is your micro-benchmark

- Depends on the level on which you are operating
- Eg: Imbench
 - ... is a Linux micro-benchmark suite
 - ... is a hypervisor macro-benchmark

Synthetic vs “Real-world” Benchmarks

- Real-world benchmarks:
 - real code taken from real problems
 - Livermore loops, SPEC, EEMBC, ...
 - execution traces taken from real problems
 - distributions taken from real use
 - file sizes, network packet arrivals and sizes
 - Caution: representative for one scenario doesn't mean for every scenario!
 - may not provide complete coverage of relevant data space
 - may be biased
- Synthetic benchmarks
 - created to simulate certain scenarios
 - tend to use random data, or extreme data
 - may represent unrealistic workloads
 - may stress or omit pathological cases

Standard vs Ad-Hoc Benchmarks

Why use ad-hoc benchmarks?

- There may not be a suitable standard
 - Eg lack of standardised multi-tasking workloads
- Cannot run standard benchmarks
 - Limitations of experimental system
 - Resource-constrained embedded system

Why not use ad-hoc benchmarks?

- Not comparable to other work
- Poor reproducibility

Facit: Use ad-hoc BMs only if you have no choice!

- Justify your approach carefully

Benchmark Suites

- Widely used (and abused!)
- Collection of individual benchmarks, aiming to cover all of relevant data space
- Examples: SPEC CPU{92|95|2000|2006}
 - Originally aimed at evaluating processor performance
 - Heavily used by computer architects
 - Widely (ab)used for other purposes
 - Integer and floating-point suite
 - Some short, some long-running
 - Range of behaviours from memory-intensive to CPU-intensive
 - behaviour changes over time, as memory systems change
 - need to keep increasing working sets to ensure significant memory loads

Obtaining an Overall Score for a BM Suite

- How can we get a single figure of merit for the whole suite?
- Example: comparing 3 systems on suite of 2 BMs

Benchmark	System X	System Y	System Z
1	20	10	40
2	40	80	20
Total	60	90	60
Mean	30	45	30

- Does the mean make sense?
 - It does where the total (sum) execution time has meaning
 - What if the individual BMs are independent and the sum has no meaning?

Obtaining an Overall Score for a BM Suite (2)

- Individual BMs frequently normalised to baseline system
- Eg: Normalise to *System X*

Benchmark	System X		System Y		System Z	
	Abs	Rel	Abs	Rel	Abs	Rel
1	20	1.00	10	0.50	40	2.00
2	40	1.00	80	2.00	20	0.50
Mean	30	1.00	45	1.25	30	1.25

- Does the mean make sense?

Obtaining an Overall Score for a BM Suite (3)

- Individual BMs frequently normalised to baseline system
- Eg: Normalise to *System Y*

Benchmark	System X		System Y		System Z	
	Abs	Rel	Abs	Rel	Abs	Rel
1	20	2.00	10	1.00	40	4.00
2	40	0.50	80	1.00	20	0.25
Mean	30	2.50	45	1.00	30	2.13

- Does the mean make sense?

Obtaining an Overall Score for a BM Suite (4)

- Individual BMs frequently normalised to baseline system
- Eg: Normalise to *System X*
- How about the geometric mean: $\langle X \rangle = (\prod X_i)^{1/i}$

Benchmark	System X		System Y		System Z	
	Abs	Rel	Abs	Rel	Abs	Rel
1	20	1.00	10	0.50	40	2.00
2	40	1.00	80	2.00	20	0.50
Geom. mean		1.00		1.00		1.00

- Does the geometric mean make sense?

Obtaining an Overall Score for a BM Suite (5)

- Individual BMs frequently normalised to baseline system
- Eg: Normalise to *System Y*
- How about the geometric mean: $\langle X \rangle = (\prod X_i)^{1/i}$

Benchmark	System X		System Y		System Z	
	Abs	Rel	Abs	Rel	Abs	Rel
1	20	2.00	10	1.00	40	4.00
2	40	0.50	80	1.00	20	0.25
Geom. mean		1.00		1.00		1.00

- The geometric mean is invariant under normalisation
- Rule: *arithmetic* mean for *raw* numbers, *geometric* mean for *normalised*!
 - [Fleming & Wallace, 1986]

Benchmark Suite Abuse

Benchmarking Crime: Select subset of suite

- Introduces bias
 - Point of suite is to cover a range of behaviour
 - Be wary of “typical results”, “representative subset”
- Sometimes unavoidable
 - some don't build on non-standard system or fail at run time
 - some may be too big for a particular system
 - eg, don't have file system and run from RAM disk...
- Treat with extreme care!
 - can only draw limited conclusion from results
 - cannot compare with (complete) published results
 - need to provide convincing explanation why only subset

Other SPEC crimes include use for multiprocessor scalability

- run multiple SPECS on different CPUs
- what does this prove?

Partial Data

- Frequently seen in I/O benchmarks:
 - Throughput is degraded by 10%
 - “Our super-reliable stack only adds 10% overhead”
 - This is almost certainly not true. Why?
 - Why is throughput degraded?
 - latency too high
 - CPU saturated?
 - Also, changes to drivers or I/O subsystem may affect scheduling
 - interrupt coalescence: do more with fewer interrupts
 - Throughput on its own is useless

Throughput Degradation

- Scenario: Network driver or protocol stack
 - New driver reduces throughput by 10% — why?
 - Compare:
 - 100 Mb/s, 100% CPU vs 90 Mb/s, 100% CPU
 - 100 Mb/s, 20% CPU vs 90 Mb/s, 40% CPU
 - Correct figure of merit is *processing cost per unit of data*
 - Proportional to *CPU load divided by throughput*
 - Correct overhead calculation:
 - 10 µs/kb vs 11 µs/kb: *10% overhead*
 - 2 µs/kb vs 4.4 µs/kb: *120% overhead*

Benchmarking crime: Show throughput degradation only

- ... and pretend this represents total overhead

Overview

- Performance
- Benchmarking
- **Profiling**
- Performance analysis

Profiling

- Run-time collection of execution statistics
 - *invasive (requires some degree of instrumentation)*
 - *unless use hardware debugging tools or cycle-accurate simulators*
 - *therefore affects the execution it's trying to analyse*
 - *good profiling approaches minimise this interference*
- Use to identify parts of system where optimisation provides most benefit
- Complementary to microbenchmarks
- Example: gprof
 - *compiles tracing into code, to record call graph*
 - *uses statistical sampling:*
 - *on each timer tick record program counter*
 - *post execution translate this into execution-time share*

Gprof example output

```
Each sample counts as 0.01 seconds.
% cumulative self      self      total
time seconds seconds  calls  ms/call  ms/call  name
33.34      0.02      0.02    7208    0.00    0.00    open

Profiling

- Run-time collection of execution statistics
 - invasive (requires some degree of instrumentation)
 - therefore affects the execution it's trying to analyse
 - good profiling approaches minimise this interference
- Use to identify parts of system where optimisation provides most benefit
- Complementary to microbenchmarks
- Example: gprof
 - compiles tracing into code, to record call graph
 - uses statistical sampling:
 - on each timer tick record program counter
 - post execution translate this into execution-time share
- Example: oprof
 - collects hardware performance-counter readings
 - works for kernel and apps
 - minimal overhead

oprof example output

```
$ oprofile --exclude-dependent
CPU: PIII, speed 863.195 MHz (estimated)
Counted CPU_CLK_UNHALTED events (clocks processor is not halted) with a ...

Performance Monitoring Unit (PMU)

- Collects certain *events* at run time
- Typically supports many events, small number of *event counters*
 - Events refer to hardware (micro-architectural) features
 - Typically relating to instruction pipeline or memory hierarchy
 - Dozens or hundreds
 - Counter can be bound to a particular event
 - Via some configuration register
 - Typically 2–4
 - OS can sample counters
 - Counters can trigger exception on exceeding threshold

Event Examples (ARM11)

Ev #	Definition	Ev #	Definition	Ev #	Definition
0x00	I-cache miss	0x0b	D-cache miss	0x22	...
0x01	Instr. buffer stall	0x0c	D-cache writeback	0x23	Funct. call
0x02	Data depend. stall	0x0d	PC changed by SW	0x24	Funct. return
0x03	Instr. micro-TLB miss	0x0f	Main TLB miss	0x25	Funct. ret. predict
0x04	Data micro-TLB miss	0x10	Ext data access	0x26	Funct. ret. mispred
0x05	Branch executed	0x11	Load-store unit stall	0x30	...
0x06	Branch mispredicted	0x12	Write-buffer drained	0x38	...
0x07	Instr. executed	0x13	Cycl FIQ disabled	0xff	Cycle counter
0x09	D-cache acc cachable	0x14	Cycl IRQ disabled		
0x0a	D-cache access any	0x20	...		

Overview

- Performance
- Benchmarking
- Profiling
- **Performance analysis**

Significance of Measurements

All measurements are subject to random errors

- Standard scientific approach: Many iterations, *collect statistics*
- Rarely done in systems work — why?
- Computer systems tend to be *highly deterministic*
 - Repeated measurements often give identical results
 - Main exception are experiments involving WANs
- However, it is dangerous to rely on this without checking!
 - Sometimes “random” fluctuations indicate *hidden parameters*

Benchmarking crime: results with no indication of significance

Non-criminal approach:

- Show at least standard deviation of your measurements
- ... or state explicitly it was below a certain value throughout
- Admit results are insignificant unless well-separated std deviations

How to Measure and Compare Performance

Bare-minimum statistics:

- At minimum report the mean (μ) and standard deviation (σ)
 - Don't believe any effect that is less than a standard deviation
 - 10.2 ± 1.5 is not significantly different from 11.5
 - Be highly suspicious if it is less than two standard deviations
 - 10.2 ± 0.8 may not be different from 11.5
- Be *very suspicious* if reproducibility is poor (i.e. σ is *not* small)
- *Distrust* standard deviations of small iteration counts
 - standard deviations are meaningless for small number of runs
 - ... but ok if effect $\gg \sigma$
 - The proper way to check significance of differences is Student's t-test!

How to Measure and Compare Performance

Bare-minimum stats are sometimes insufficient

- Eg: Old: $\mu = 18$ sec, New: $\mu = 6$ sec

Cumulative distribution function (CDF)

Courtesy Robert Grimm

How to Measure and Compare Performance

Obtaining meaningful execution times:

- Make sure execution times are long enough
 - What is the granularity of your time measurements?
 - make sure the effect you're looking for is much bigger
 - many repetitions won't help if your effect is dominated by clock resolution
 - do many repetitions in a tight loop if necessary

Example: gzip from SPEC CPU2000

Observations?

- First iteration is special
 - Warm up caches to get reliable data
- Clock resolution 50ms
 - will not be able to observe any effects that account for less than 0.1 sec

Lesson?

- Need a mental model of the system
 - Here: repeated runs should give the same result
- Find reason (hidden parameters) if results do not comply!

How to Measure and Compare Performance

Noisy data:

- sometimes it isn't feasible to get a "clean" system
 - e.g. running apps on a "standard configuration"
 - this can lead to very noisy results, large standard deviations

Possible ways out:

- ignoring lowest and highest result
- taking the floor of results
 - makes only sense if you're looking for minimum
 - but beware of difference-taking!

Both of these are dangerous, use with great care!

- Only if you know what you are doing
 - need to give a convincing explanation of why this is justified
- Only if you explicitly state what you've done in your paper/report

How to Measure and Compare Performance

Check outputs!

- Benchmarks must check results are correct!
 - Sometimes things are very fast because no work is done!
 - Beware of compiler optimisations, implementation bugs
- Sometimes checking all results is infeasible
 - eg takes too long, checking dominates effect you're looking for
 - check at least *some* runs
 - run same setup with checks en/disabled

How to Measure and Compare Performance

Vary inputs!

- Easy to produce low standard deviations by using identical runs
 - but this is often not representative
 - can lead to unrealistic caching effects
 - especially in benchmarks involving I/O
 - disks are notorious for this
 - controllers do caching, pre-fetching etc out of control of OS
- Good ways to achieve variations:
 - time stamps for randomising inputs (but see below!)
 - varying order:
 - forward vs backward
 - sequential with increasing strides
 - random access
 - best is to use combinations of the above, to ensure that results are sane

How to Measure and Compare Performance

Ensure runs are comparable and reproducible:

- Avoid true randomness!
 - tends to lead to different execution paths or data access patterns
 - makes results non-reproducible
 - makes impossible to fairly compare results from different implementations!
 - exceptions exist
 - crypto algorithms are designed to have execution path independent of inputs
- Pseudo-random is good for benchmarking
 - reproducible sequence of "random" inputs
 - capture sequence and replay for each run
 - use pseudo-random generator with same seed

How to Measure and Compare Performance

Environment

- Ensure system is quiescent
 - to the degree possible, turn off any unneeded functionality
 - run Unix systems in single-user mode
 - turn off wireless, disconnect networks, put disk to sleep, etc
 - Be aware of self-interference
 - eg logging benchmark results may wake up disk...
- Ensure compared runs start from the same system state (as far as possible)
 - back-to-back processes may *not* find the system in the same state

Real-World Example

Benchmark:

- `300.two1f` from SPEC CPU2000 suite

Platform:

- Dell Latitude D600
 - Pentium M @ 1.8GHz
 - 32KiB L1 cache, 8-way
 - 1MiB L2 cache, 8-way
 - DDR memory @ effective 266MHz
- Linux kernel version 2.6.24

Methodology:

- Multiple identical runs for statistics...

two1f on Linux: What's going on?

20% variation in execution time between "identical" runs!

two1f on Linux:

Performance counters are your friends!

twolf on Linux:

Subtract 221 cy (123ns) for each cache miss

What's going on???

twolf on Linux: Lessons?

- Pointer to problem was standard deviation
 - σ for "twolf" was much higher than normal for SPEC programs
- Standard deviation did not conform to mental model
 - Shows the value of verifying that model holds
 - Correcting model improved results dramatically
- Shows danger of assuming reproducibility without checking!
- Facit: **Always** collect and analyse standard deviations!

How to Measure and Compare Performance

Vary only one thing at a time!

- Typical example: used a combination of techniques to improve system
 - what can you learn from a 20% overall improvement?
- Need to run sequence of evaluations, looking at individual changes
 - identify contribution and relevance
 - understand how they combine to an overall effect
 - they may enhance or counter-balance each other
 - make sure you understand what's going on!!!!

Record all configurations and data!

- May have overlooked something at first
- May develop better model later
 - could be much faster to re-analyse existing data than re-run all benchmarks

How to Measure and Compare Performance

Measure as directly as possible:

- Eg, when looking at effects of pinning TLB entries
 - don't just look at overall execution time (combination of many things)
 - use performance counter to compare
 - TLB misses
 - cache misses (from page table reloads)
 - ...
- Cannot always measure directly
 - eg, actual TLB-miss cost not known
 - extrapolate by artificially reducing TLB size
 - eg by pinning useless entries

How to Measure and Compare Performance

Avoid incorrect conclusions from pathological cases

→ Typical cases:

- sequential access optimised by underlying hardware/disk controller...
- potentially massive differences between sequentially up/down
 - pre-fetching by processor, disk cache
- random access may be an unrealistic scenario that destroys performance
 - for file systems
- powers of two may be particularly good or particularly bad for strides
 - often good for cache utilisation
 - minimise number of cache lines used
 - often bad for cache utilisation
 - maximise cache conflicts
- similarly just-off powers (2^n-1 , 2^n+1)

→ What is “pathological” depends a lot on what you're measuring

- e.g. caching in underlying hardware

How to Measure and Compare Performance

Use a model

→ You need a (mental or explicit) model of the behaviour of your system

- benchmarking should aim to support or disprove that model
- need to think about this in selecting data, evaluating results
- eg: I/O performance dependent on FS layout, caching in controller...
- cache sizes (HW & SW caches)
- buffer sizes vs cache size

→ Should tell you the size of what to expect

- you should understand that a 2ns cache miss penalty can't be right

Example: Memory Copy

How to Measure and Compare Performance

Understand your results!

→ Results you don't understand will almost certainly hide a problem

- Never publish results you don't understand
 - chances are the reviewers understand them, and will reject the paper
 - maybe worse: someone at the conference does it
 - this will make you look like an idiot
 - of course, if this happens you *are* an idiot!

Loop and Timing Overhead

Ensure that measuring overhead does not affect results:

- Cost of accessing clock may be significant
- Loop overhead may be significant
- Stub overhead may be significant

Approaches:

- May iterations in tight loop
- Measure and eliminate timer overhead
- Measure and eliminate loop overhead
- Eliminate effect of any instrumentation code

Eliminating Overhead

```
t0 = time();
for (i=0; i<MAX; i++) {
    asm(nop);
}
t1 = time();
for (i=0; i<MAX; i++) {
    asm(syscall);
}
t2 = time();
printf("Cost is %dus\n", (t2-2*t1+t0)*1000000/MAX);
```

Beware of compiler optimizations!

Relative vs Absolute Data

From a real paper (IEEE CCNC'09):

- No data other than this figure
- No figure caption
- Only explanation in text:
 - "The L4 overhead compared to VLX ranges from a 2x to 20x factor depending on the Linux system call benchmark"
- No definition of "overhead factor"
- No native Linux data

Benchmarking crime: Relative numbers only

- Makes it impossible to check whether results make sense
- How hard did they try to get the competitor system to perform?
 - Eg, did they run it with default build parameters (debugging enabled)?

Benchmarking Ethics

- Do compare with published competitor data, but...
 - Ensure comparable setup
 - Same hardware (or *convincing* argument why it doesn't matter)
 - you may be looking at an aspect the competitor didn't focus on
 - eg: they designed for large NUMA, you optimise for embedded
- Be ultra-careful when benchmarking competitor's system yourself
 - Are you sure you're running the competitor system optimally?
 - you could have the system mis-configured (eg debugging enabled)
 - Do your results match their (published or else) data?
 - Make sure you understand exactly what is going on!
 - Eg use profiling/tracing to understand source of difference
 - Explain it!

Benchmarking crime: Unethical benchmarking of competitor

- Lack of care is unethical too!

Other Ways to Cheat With Benchmarks

- Benchmark-specific optimisations
 - Popular with compiler-writers
 - Recognise particular benchmark
 - Insert BM-specific hand-optimised code
- End-user benefit: Zero
- Rarely an issue in OS area

What Is “Good”?

- Easy if there are established and published benchmarks
 - Eg your improved algorithm beats best published Linux data by x%
 - But are you sure that it doesn't lead to worse performance elsewhere?
 - important to run complete benchmark suites
 - think of everything that could be adversely effected, and *measure!*
- Tricky if no published standard
 - Can run competitor/incumbent
 - eg run lmbench, kernel compile etc on your modified Linux and standard Linux
 - but be *very careful* to avoid running the competitor sub-optimally!
 - Establish performance limits
 - ie compare against optimal scenario
 - micro-benchmarks or profiling can be highly valuable here!

Real-World Example: Virtualization Overhead

- Symbian null-syscall microbenchmark:
 - native: 0.24µs, virtualized: 0.79µs
 - 230% overhead — good or bad?
- ARM11 processor runs at 368 MHz:
 - Native: 0.24µs = 93 cy
 - Virtualized: 0.79µs = 292 cy
 - Overhead: 0.55µs = 199 cy
 - Cache-miss penalty ≈ 20 cy
- Model:
 - native: 2 mode switches, 0 context switches, 1 x save+restore state
 - virtualized: 4 mode switches, 2 context switches, 3 x save+restore state
 - expected overhead?

Performance Counters are Your Friends!

Good or bad?

Counter	Native	Virtualized	Difference
Branch miss-pred	1	1	0
D-cache miss	0	0	0
I-cache miss	0	1	1
D-µTLB miss	0	0	0
I-µTLB miss	0	0	0
Main-TLB miss	0	0	0
Instructions	30	125	95
D-stall cycles	0	27	27
I-stall cycles	0	45	45
Total Cycles	93	292	199

More of the Same...

First step: improve representation!

Benchmark	Native	Virtualized
Context switch [1/s]	615046	444504
Create/close [µs]	11	15
Suspend [10ns]	81	154

Benchmark	Native	Virtualized	Difference	Overhead
Context switch [µs]	1.63	2.25	0.62	39%
Create/close [µs]	11	15	4	36%
Suspend [µs]	0.81	1.54	0.73	90%

More of the Same...

Then represent the overheads in the right units...

Benchmark	Native	Virt.	Diff [µs]	Diff [cy]	# sysc	Cy/sysc
Context switch [µs]	1.63	2.25	0.62	230	1	230
Create/close [µs]	11	15	4	1472	2	736
Suspend [µs]	0.81	1.54	0.73	269	1	269

Further analysing the create/close benchmark:

- guest dis/enables interrupts 22 times
 - extra instructions required to manipulate virtual interrupt flag
 - account for most of extra overhead

Yet Another One...

Benchmark	Native [µs]	Virt. [µs]	Overhead
TDes16_Num0	1.2900	1.2936	0.28%
TDes16_RadixHex1	0.7110	0.7129	0.27%
TDes16_RadixDecimal2	1.2338	1.2373	0.28%
TDes16_Num_RadixOctal3	0.6306	0.6324	0.28%
TDes16_Num_RadixBinary4	1.0088	1.0116	0.27%
TDesC16_Compare5	0.9621	0.9647	0.27%
TDesC16_CompareF7	1.9392	1.9444	0.27%
TdesC16_MatchF9	1.1060	1.1090	0.27%

- Note: these are purely user-level operations!
 - What's going on?

Yet Another One...

Benchmark	Native [µs]	Virt. [µs]	Overhead	Per tick
TDes16_Num0	1.2900	1.2936	0.28%	2.8 µs
TDes16_RadixHex1	0.7110	0.7129	0.27%	2.7 µs
TDes16_RadixDecimal2	1.2338	1.2373	0.28%	2.8 µs
TDes16_Num_RadixOctal3	0.6306	0.6324	0.28%	2.8 µs
TDes16_Num_RadixBinary4	1.0088	1.0116	0.27%	2.7 µs
TDesC16_Compare5	0.9621	0.9647	0.27%	2.7 µs
TDesC16_CompareF7	1.9392	1.9444	0.27%	2.7 µs
TdesC16_MatchF9	1.1060	1.1090	0.27%	2.7 µs

Note: these are purely user-level operations!

- What's going on?
- Timer tick is 1000 Hz
- Overhead from virtualizing timer interrupt!
- Good or bad?

Lessons Learned

- Ensure stable results
 - repeat for good statistics
 - investigate source of apparent randomness
- Have a model of what you expect
 - investigate if behaviour is different
 - unexplained effects are likely to indicate problems — don't ignore them!
- Tools are your friends
 - performance counters
 - simulators
 - traces
 - spreadsheets
