S2/2013 Week 2: Caches:

What every OS Designer Must Know

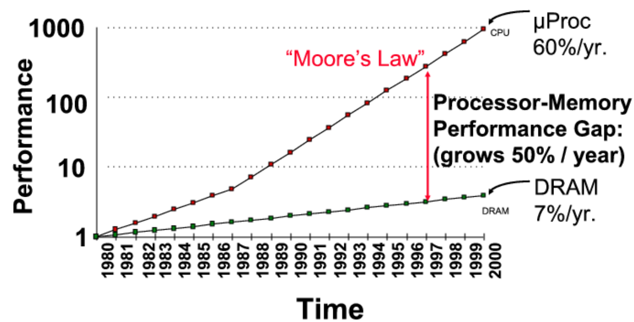
The Memory Wall



Multicore offsets stagnant per-core performance with proliferation of cores

- Basic trend is unchanged

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Caching

- Cache is fast (1–5 cycle access time) memory sitting between fast registers and slow RAM (10–100 cycles access time)
- Holds recently-used data or instructions to save memory accesses
- Matches slow RAM access time to CPU speed if high **hit rate** *(> 90%)*
- Is hardware maintained and (mostly) transparent to software
- Sizes range from few KiB to several MiB.
- Usually a hierarchy of caches (2–5 levels), on- and off-chip

Good overview of implications of caches for operating systems: [Schimmel 94]

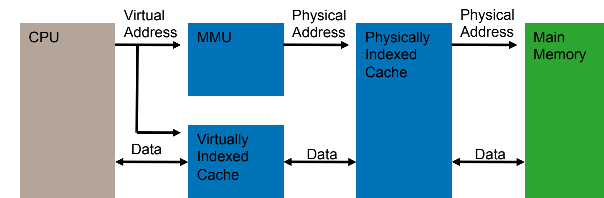
©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Cache Organization

- Data transfer unit between registers and L1 cache: ≤ 1 word (1–16B)
- Cache *line* is transfer unit between cache and RAM (or lower cache)
  - typically 16–32 bytes, sometimes 128 bytes and more
- Line is also unit of storage allocation in cache
- Each line has associated control info:
  - valid bit
  - modified bit
  - tag
- Cache improves memory access by:
  - absorbing most reads (increases bandwidth, reduces latency)
  - making writes asynchronous (hides latency)
  - clustering reads and writes (hides latency)

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

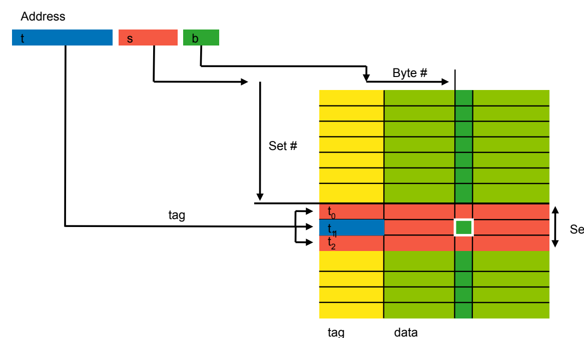
Cache Access



- **Virtually indexed:** looked up by *virtual address*
  - operates concurrently with address translation
- **Physically indexed:** looked up by *physical address*
  - requires result of address translation
- Usually have hierarchy: L1 (closest to core), … Ln (closest to RAM)
  - different levels may use different addresses

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Cache Indexing



- The *tag* is used to distinguish lines of set…
- Consists of high-order bits not used for indexing

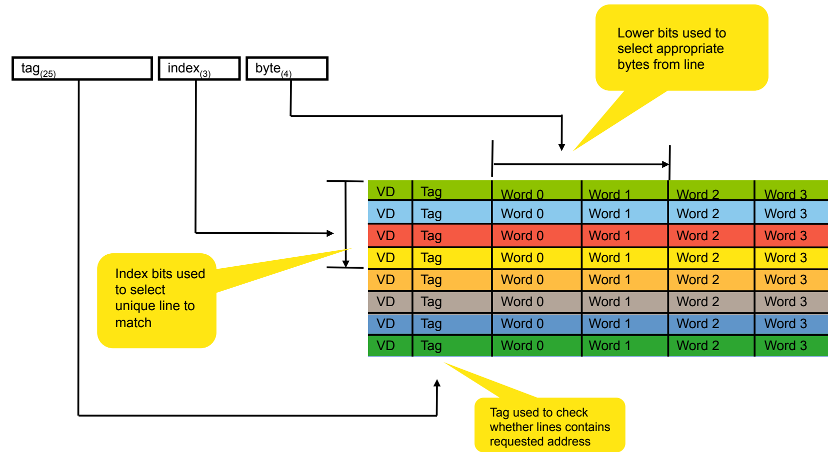
©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Cache Indexing

- Address hashed to produce index of *line set*
- Associative lookup of line within set
- *n* lines per set: *n-way set-associative cache*
  - typically n = 1 … 5, some embedded processors use 32-64
  - n = 1 is called direct mapped
  - n = ∞ is called fully associative (unusual for I/D caches)
- Hashing must be simple (complex hardware is slow)
  - use least-significant bits of address

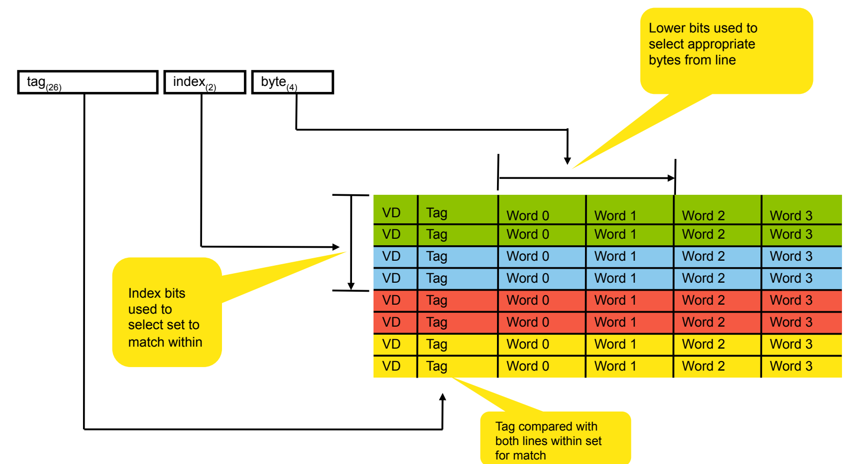
©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Cache Indexing: Direct Mapped



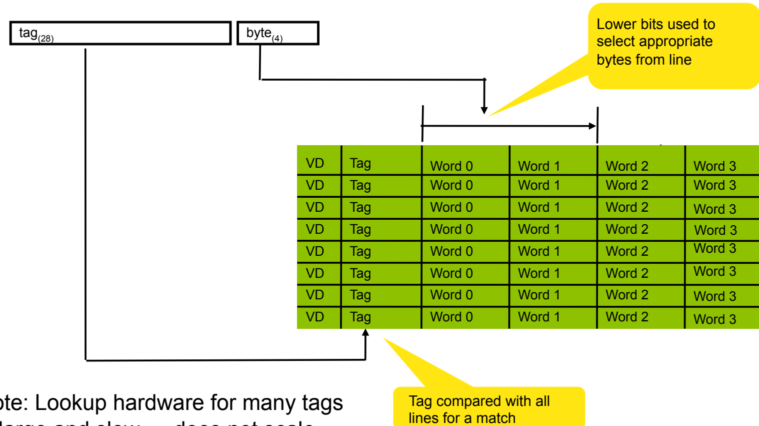
©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License
UNSW

Cache Indexing: 2-Way Associative



©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License
UNSW

Caching Index: Fully Associative

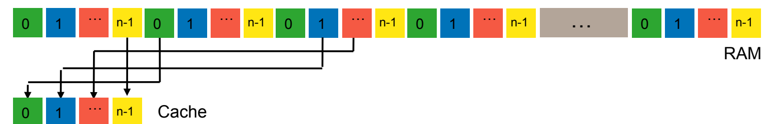


Note: Lookup hardware for many tags is large and slow ⇒ does not scale

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License
UNSW

Cache Mapping

- Multiple memory locations map to the same cache line

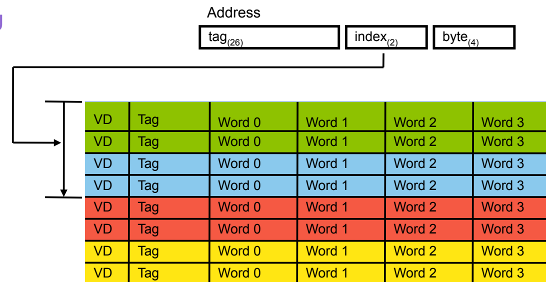


- Locations mapping to cache set *i* are said to be of *colour i*
- *n-way* associative cache can hold *n lines* of the same colour
- Types of cache misses ("the four Cs"):
  - **Compulsory miss:** data cannot be in the cache (if infinite size)
    - first access (after flush)
  - **Capacity miss:** all cache entries are in use by other data
    - would not miss on infinite-size cache
  - **Conflict miss:** all lines of the correct colour are in use by other data
    - would not miss on fully-associative cache
  - **Coherence miss:** miss forced by hardware coherence protocol

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License
UNSW

Cache Replacement Policy

- Indexing (using address) points to specific line set
- On miss (all lines of set are valid): *replace* existing line
- Replacement strategy must be simple (hardware!)
  - dirty bit determines whether line must be written back
  - typical policies:
    - pseudo-LRU
    - FIFO
    - random
    - toss clean



©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Cache Write Policy

- Treatment of store operations
  - **write back:** Stores only update cache;
    memory is updated once dirty line is replaced (flushed)
    - ☑ clusters writes
    - ⌘ memory inconsistent with cache
    - ⌘ unsuitable for most multi-processor designs
  - **write through:** stores update cache and memory immediately
    - ☑ memory is always consistent with cache
    - ⌘ increased memory/bus traffic
- On store to a line not presently in cache (write miss):
  - **write allocate:** allocate a cache line and store there
    - typically requires reading line into cache first!
  - **no allocate:** store directly to memory, bypassing the cache
- Typical combinations:
  - write-back & write-allocate
  - write-through & no allocate

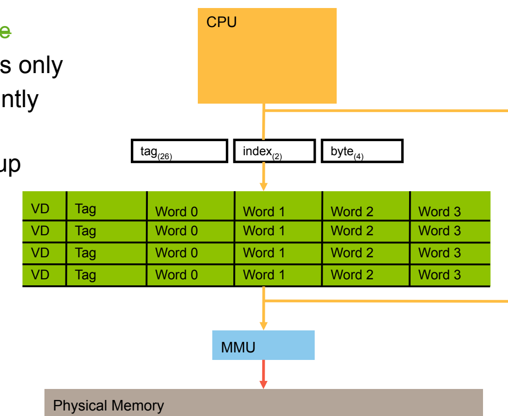
Cache Addressing Schemes

- For simplicity assumed so far that cache only sees one type of address: virtual or physical
- However, *indexing and tagging can use different addresses!*
- Four possible addressing schemes:
  - virtually-indexed, virtually-tagged (VV) cache
  - virtually-indexed, physically-tagged (VP) cache
  - physically-indexed, virtually-tagged (PV) cache
  - physically-indexed, physically-tagged (PP) cache
- PV caches can make sense only with unusual MMU designs
  - not considered any further

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Virtually-Indexed, Virtually-Tagged Cache

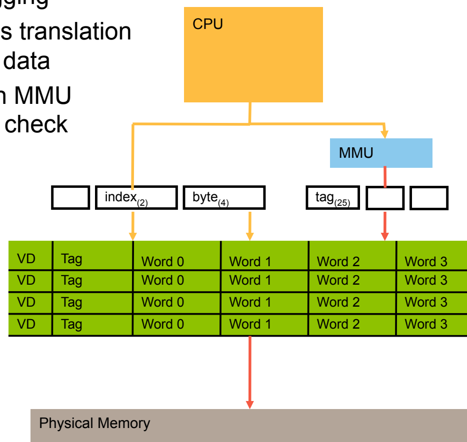
- Also called *virtually-addressed cache*
- Various incorrect names in use:
  - ~~virtual cache~~
  - ~~virtual address cache~~
- Uses virtual addresses only
- Can operate concurrently with MMU
- Still needs MMU lookup for access rights
- Used for on-core L1



©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Virtually-Indexed, Physically-Tagged Cache

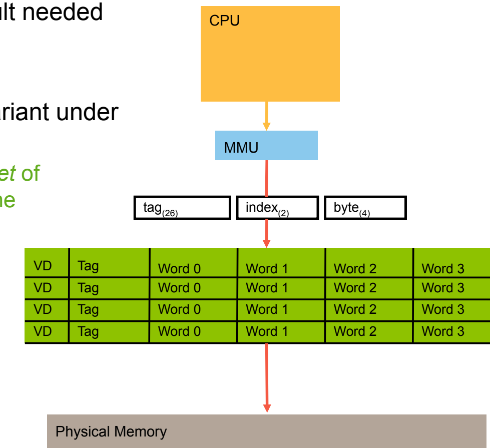
- Virtual address for accessing line (lookup)
- Physical address for tagging
- Needs complete address translation for looking up retrieving data
- Indexing concurrent with MMU use MMU output for tag check
- Used for on-core L1



©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Physically-Indexed, Physically-Tagged Cache

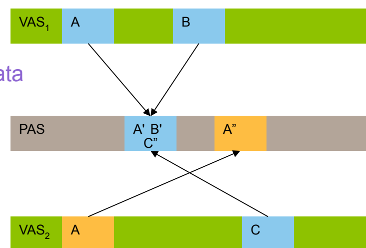
- Only uses physical addresses
- Address translation result needed to begin lookup
- Typically used off-core
- Note: page offset is invariant under address translation
  - if index bits are a *subset* of the offset bits, PP cache lookup doesn't need MMU result!
  - VP=PP in this case fast and suitable for on-core use (L1)



©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Cache Issues

- Caches are managed by hardware transparently to software
  - OS doesn't have to worry about them, ~~right?~~ **Wrong!**
- Software-visible cache effects:
  - performance
  - *homonyms*:
    - same address, different data
    - can affect correctness!
  - *synonyms (aliases)*:
    - different address, same data
    - can affect correctness!

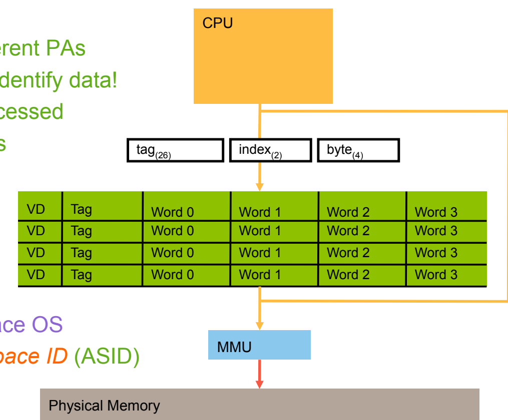


©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Virtually-Indexed Cache Issues

Homonyms – same name for different data:

- Problem: VA used for indexing is context-dependent
  - same VA refers to different PAs
  - tag does not uniquely identify data!
  - wrong data may be accessed
  - an issue for most OSes
- Homonym prevention:
  - flush cache on each context switch
  - force non-overlapping address-space layout
    - single-address-space OS
  - *tag* VA with *address-space ID* (ASID)
    - makes VAs global

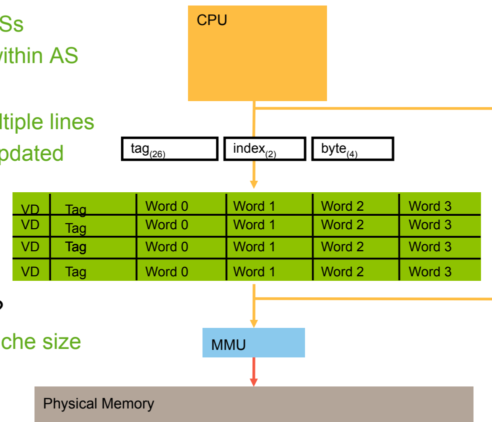


©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Virtually-Indexed Cache Issues

Synonyms – multiple names for same data:

- Several VAs map to the same PA
  - frame shared between ASs
  - frame multiply mapped within AS
- May access stale data!
  - same data cached in multiple lines
  - on write, one synonym updated
  - read on other synonym returns old value
  - physical tags don't help!
  - ASIDs don't help!
- Are synonyms a problem?
  - depends on page and cache size
  - no problem for R/O data or I-caches

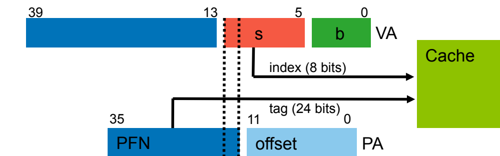


©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

UNSW

Example: MIPS R4x00 Synonyms

- ASID-tagged, on-chip VP cache
  - 16 KiB cache, 2-way set associative, 32 B line size
  - 4 KiB (base) page size
  - size/associativity = 16/2 KiB = 8 KiB > page size
    - 16 KiB / (32 B/line) = 512 lines = 256 sets ⇒ 8 index bits (12..5)
    - overlap of tag bits and index bits, but from different addresses!

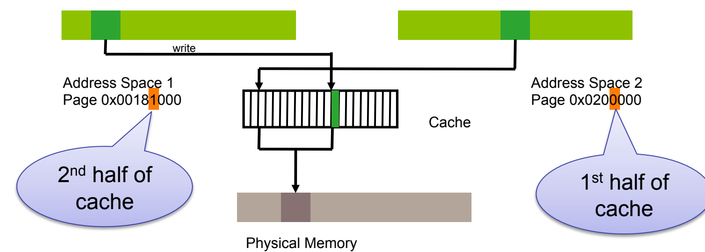


- Remember, index determines location of data in cache
  - tag only confirms hit
  - synonym problem iff $VA_{12} \neq VA'_{12}$
  - similar issues on other processors

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

UNSW

Address Mismatch Problem: Aliasing

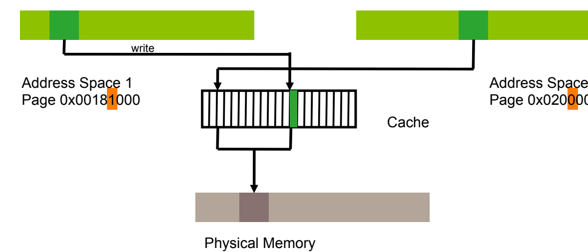


- Page aliased in different address spaces
  - AS_1: VA_{12} = 1, AS_2: VA_{12} = 0
- One alias gets modified
  - in a write-back cache, other alias sees stale data
  - lost-update problem

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

UNSW

Address Mismatch Problem: Re-Mapping



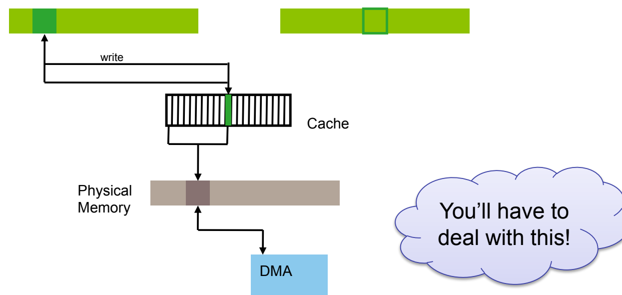
- Unmap page with a dirty cache line
- Re-use (remap) frame for a different page (in same or different AS)
- Write to new page
  - without mismatch, new write will overwrite old (hits same cache line)
  - with mismatch, order can be reversed: "*cache bomb*"

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

UNSW

DMA Consistency Problem

NICTA



- DMA (normally) uses physical addresses and bypasses cache
  - CPU access inconsistent with device access
  - need to flush cache before device write
  - need to invalidate cache before device read

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License
UNSW

Avoiding Synonym Problems

NICTA

- Flush cache on context switch
  - doesn't help for aliasing *within* address space!
- Detect synonyms and ensure:
  - all read-only, or
  - only one synonym mapped
- Restrict VM mapping so synonyms map to same cache set
  - eg on R4x00: ensure $VA_{12} = PA_{12}$
- Hardware synonym detection
  - e.g. Cortex A9: store overlapping tag bits of both addresses & check
  - "physically"-addressed

UNSW

Summary: VV Caches

NICTA

☑ Fastest (don't rely on TLB for retrieving data)
  - ⌘ still need TLB lookup for protection
  - ⌘ … or alternative mechanism for providing protection

⌘ Suffer from synonyms and homonyms
  - ⌘ requires flushing on context switches
    - ⌘ makes context switches expensive
    - ⌘ may even be required on kernel→user switch
  - … or guarantee no synonyms and homonyms

⌘ Require TLB lookup for write-back!

- Used on MC68040, i860, ARM7/ARM9/StrongARM/Xscale
- Used for I-caches on several other architectures (Alpha, Pentium 4)

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License
UNSW

Summary: Tagged VV Caches

NICTA

- Add ASID as part of tag
- On access, compare with CPU's ASID register

☑ Removes homonyms
  - ☑ potentially better context-switching performance
  - ⌘ ASID recycling still needs flush

⌘ Doesn't solve synonym problem (but that's less severe)

⌘ Doesn't solve write-back problem

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License
UNSW

Summary: VP Caches

- Medium speed
  - ☑ lookup in parallel with address translation
  - ⌘ tag comparison after address translation
- ☑ No homonym problem
- ⌘ Potential synonym problem
- ⌘ Bigger tags (cannot leave off set-number bits)
  - ⌘ increases area, latency, power consumption
- Used on most modern architectures for L1 cache

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Summary: PP Caches

- ⌘ Slowest
  - ⌘ requires result of address translation before lookup starts
- ☑ No synonym problem
- ☑ No homonym problem
- ☑ Easy to manage
- ☑ If small or highly associative index can be in parallel with translation
  - all index bits come from page offset
  - combines advantages of VV and PP cache
  - useful for con-core L1 cache (Itanium, Core i7)
- ☑ Cache can use *bus snooping* to receive/supply DMA data
- ☑ Usable as post-MMU cache with any architecture

For an in-depths coverage see [Wiggins 03]

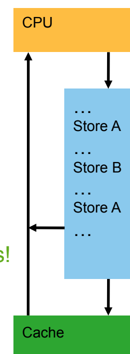
Write Buffer

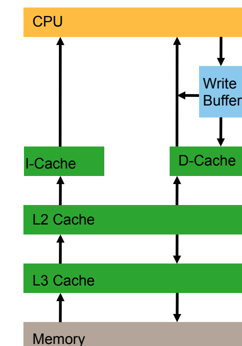
- Store operations can take a long time to complete
  - eg if a cache line must be read or allocated
- Can avoid stalling the CPU by buffering writes
- *Write buffer* is a FIFO *queue of incomplete stores*
  - also called *store buffer* or *write-behind buffer*
- Can also read intermediate values out of buffer
  - to service lead of a value that is still in write buffer
  - avoids unnecessary stalls of load operations
- Implies that memory contents are temporarily stale
  - on a multiprocessor, CPUs see different order of writes!
  - "weak store order", to be revisited in SMP context



©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

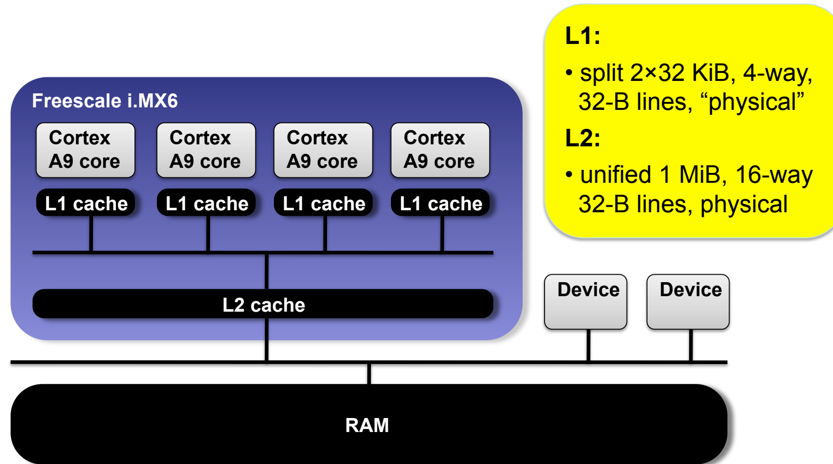
Cache Hierarchy

- Hierarchy of caches to balance memory accesses:
  - small, fast, virtually-indexed L1
  - large, slow, physically indexed L2–L5
- Each level reduces and clusters traffic
- L1 typically split into I- and D-caches
  - "Harvard architecture"
  - requirement of pipelining
- Other levels tend to be unified
- Chip multiprocessors often share on-chip L2, L3



©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Sabre (Cortex A9) System Architecture



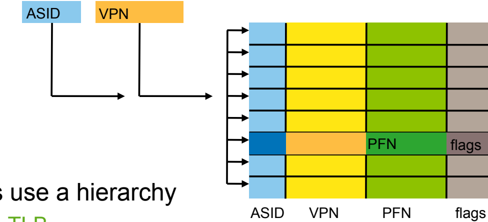
L1:
- split 2×32 KiB, 4-way, 32-B lines, “physical”

L2:
- unified 1 MiB, 16-way 32-B lines, physical

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

Translation Lookaside Buffer (TLB)

- TLB is a (VV) cache for page-table entries
- TLB can be
  - hardware loaded, transparent to OS
  - software loaded, maintained by OS
- TLB can be:
  - split: I- and D-TLBs
  - unified
- Modern architectures use a hierarchy
  - tiny (1-4 entries) L1 TLB
    - typically split, hardware loaded
  - larger (64-128 entries) L2 TLB
    - unified, hard- or software loaded



©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

TLB Issues: Associativity

- First TLB (VAX-11/780 [Clark, Emer 85]) was 2-way associative
- Most modern architectures have fully-associative TLBs
- Exceptions:
  - Intel x86: 4-way
  - IBM RS/6000: 2-way
- Reasons:
  - modern architectures tend to support multiple page sizes
    - “superpages”
    - better utilises TLB entries
  - TLB lookup done without knowing the page’s base address
  - set associativity loses speed advantage
- x86 uses separate L1 TLBs for each page size
  - 1 each I-TLB and D-TLB for 4 KiB and 2/4 MiB (4 L1 TLBs)
  - unified L2 TLB
  - all 4-way associative

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

TLB Size (I-TLB + D-TLB)

Architecture	*TLB Size*	*Page Size*	*TLB Coverage*
VAX	64–256	512B	32–128KiB
ix86	32–32+64	4KiB+4MiB	128–128+256KiB
MIPS	96–128	4KiB–16MiB	384KiB–...
SPARC	64	8KiB–4MiB	512KiB–...
Alpha	32–128+128	8KiB–4MiB	256KiB–...
RS/6000	32+128	4KiB	128+512KiB
Power-4/G5	128	4KiB+16MiB	512KiB–...
PA-8000	96+96	4KiB–64MiB	
Itanium	64+96	4KiB–4GiB	

Not much growth in 20 years!

©2011 Gernot Heiser UNSW/NICTA. Distributed under Creative Commons Attribution License

TLB Size (I-TLB + D-TLB)

TLB coverage

- Memory sizes are increasing
- Number of TLB entries are roughly constant
- Page sizes are steady
  - 4 KiB, although larger on SPARC, Alpha
- Consequences:
  - total amount of RAM mapped by TLB is not changing much
  - fraction of RAM mapped by TLB is shrinking dramatically!
  - Modern architectures have very low TLB coverage!
- Also, many 64-bit RISC architectures have software-loaded TLBs
  - general increase in TLB miss handling cost
- The TLB can become a bottleneck
