

# System Calls

THE UNIVERSITY OF  
NEW SOUTH WALES

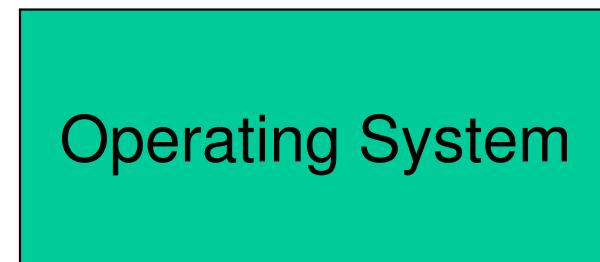

# Learning Outcomes

- A high-level understanding of System Calls
  - Mostly from the user's perspective
    - From textbook (section 1.6)
- Exposure architectural details of the MIPS R3000
  - Detailed understanding of the exception handling mechanism
    - From "Hardware Guide" on class web site
- Understanding of the existence of compiler function calling conventions
  - Including details of the MIPS 'C' compiler calling convention
- Understanding of how the application kernel boundary is crossed with system calls in general
  - Including an appreciation of the relationship between a case study (OS/161 system call handling) and the general case.

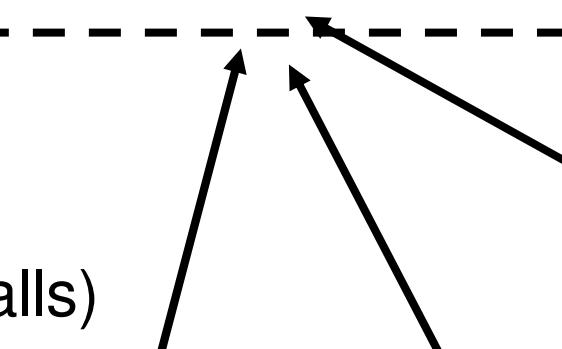

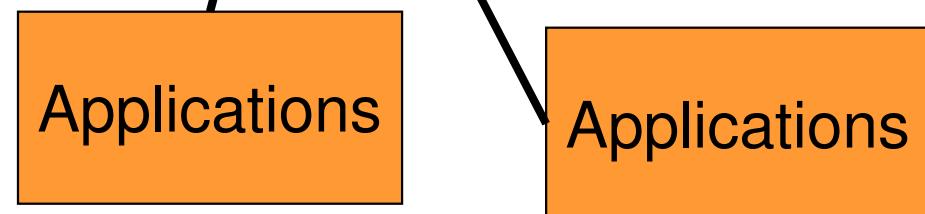

# Operating System System Calls

Kernel Level

Requests  
(System Calls)

User Level

THE UNIVERSITY OF  
NEW SOUTH WALES

# System Calls

- Can be viewed as special function calls
  - Provides for a controlled entry into the kernel
  - While in kernel, they perform a privileged operation
  - Returns to original caller with the result
- The system call interface represents the abstract machine provided by the operating system.

# A Brief Overview of Classes System Calls

- From the user's perspective
  - Process Management
  - File I/O
  - Directories management
  - Some other selected Calls
  - There are many more
    - On Linux, see `man syscalls` for a list

# Some System Calls For Process Management

## Process management

Call	Description
pid = fork()	Create a child process identical to the parent
pid = waitpid(pid, &statloc, options)	Wait for a child to terminate
s = execve(name, argv, environp)	Replace a process' core image
exit(status)	Terminate process execution and return status

# Some System Calls For File Management

## File management

Call	Description
<code>fd = open(file, how, ...)</code>	Open a file for reading, writing or both
<code>s = close(fd)</code>	Close an open file
<code>n = read(fd, buffer, nbytes)</code>	Read data from a file into a buffer
<code>n = write(fd, buffer, nbytes)</code>	Write data from a buffer into a file
<code>position = lseek(fd, offset, whence)</code>	Move the file pointer
<code>s = stat(name, &amp;buf)</code>	Get a file's status information

# Some System Calls For Directory Management

## Directory and file system management

Call	Description
<code>s = mkdir(name, mode)</code>	Create a new directory
<code>s = rmdir(name)</code>	Remove an empty directory
<code>s = link(name1, name2)</code>	Create a new entry, name2, pointing to name1
<code>s = unlink(name)</code>	Remove a directory entry
<code>s = mount(special, name, flag)</code>	Mount a file system
<code>s = umount(special)</code>	Unmount a file system

# Some System Calls For Miscellaneous Tasks

## Miscellaneous

Call	Description
<code>s = chdir(dirname)</code>	Change the working directory
<code>s = chmod(name, mode)</code>	Change a file's protection bits
<code>s = kill(pid, signal)</code>	Send a signal to a process
<code>seconds = time(&amp;seconds)</code>	Get the elapsed time since Jan. 1, 1970

# System Calls

- A stripped down shell:

```
while (TRUE) {  
    type_prompt( );  
    read_command (command, parameters) /* repeat forever */  
  
    if (fork() != 0) {  
        /* Parent code */  
        waitpid( -1, &status, 0); /* display prompt */  
    } else {  
        /* Child code */  
        execve (command, parameters, 0); /* input from terminal */  
    }  
}
```

# System Calls

UNIX	Win32	Description
fork	CreateProcess	Create a new process
waitpid	WaitForSingleObject	Can wait for a process to exit
execve	(none)	CreateProcess = fork + execve
exit	ExitProcess	Terminate execution
open	CreateFile	Create a file or open an existing file
close	CloseHandle	Close a file
read	ReadFile	Read data from a file
write	WriteFile	Write data to a file
lseek	SetFilePointer	Move the file pointer
stat	GetFileAttributesEx	Get various file attributes
mkdir	CreateDirectory	Create a new directory
rmdir	RemoveDirectory	Remove an empty directory
link	(none)	Win32 does not support links
unlink	DeleteFile	Destroy an existing file
mount	(none)	Win32 does not support mount
umount	(none)	Win32 does not support mount
chdir	SetCurrentDirectory	Change the current working directory
chmod	(none)	Win32 does not support security (although NT does)
kill	(none)	Win32 does not support signals
time	GetLocalTime	Get the current time

## Some Win32 API calls

THE UNIVERSITY OF  
NEW SOUTH WALES

# The MIPS R2000/R3000

- Before looking at system call mechanics in some detail, we need a basic understanding of the MIPS R3000

# MIPS R3000

- Load/store architecture
  - No instructions that operate on memory except load and store
  - Simple load/stores to/from memory from/to registers
    - Store word: **sw r4, (r5)**
      - Store contents of r4 in memory using address contained in register r5
    - Load word: **lw r3, (r7)**
      - Load contents of memory into r3 using address contained in r7
      - Delay of one instruction after load before data available in destination register
        - » Must always be an instruction between a load from memory and the subsequent use of the register.
    - **lw, sw, lb, sb, lh, sh, ...**

# MIPS R3000

- Arithmetic and logical operations are register to register operations
  - E.g., add r3, r2, r1
  - No arithmetic operations on memory
- Example
  - **add r3, r2, r1**  $\Rightarrow r3 = r2 + r1$
- Some other instructions
  - **add, sub, and, or, xor, sll, srl**

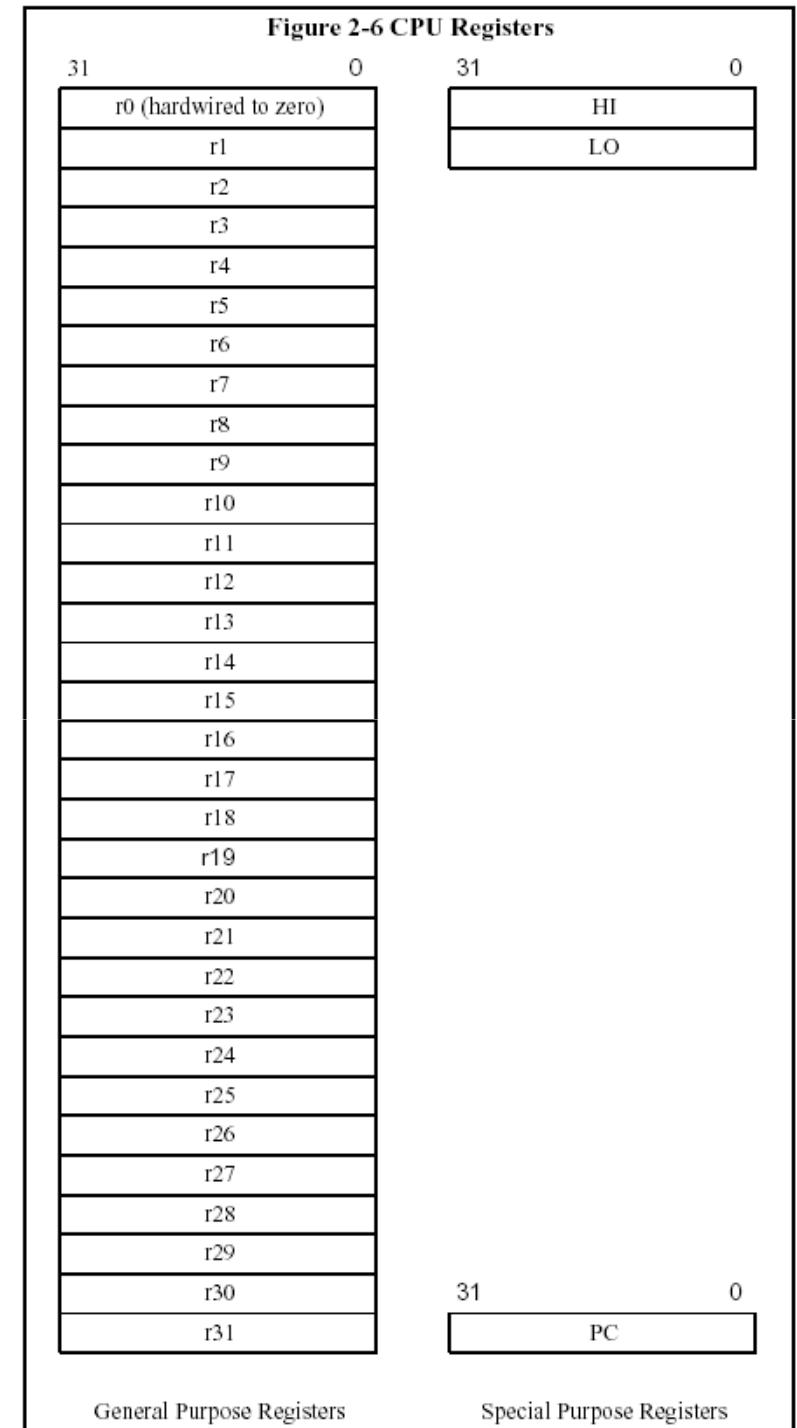

# MIPS R3000

- All instructions are encoded in 32-bit
- Some instructions have *immediate* operands
  - Immediate values are constants encoded in the instruction itself
  - Only 16-bit value
  - Examples
    - Add Immediate: `addi r2, r1, 2048`  
 $\Rightarrow r2 = r1 + 2048$
    - Load Immediate : `li r2, 1234`  
 $\Rightarrow r2 = 1234$

# MIPS Registers

- User-mode accessible registers
  - 32 general purpose registers
    - r0 hardwired to zero
    - r31 the *link* register for jump-and-link (JAL) instruction
  - HI/LO
    - $2 * 32$ -bits for multiply and divide
  - PC
    - Not directly visible
    - Modified implicitly by jump and branch instructions

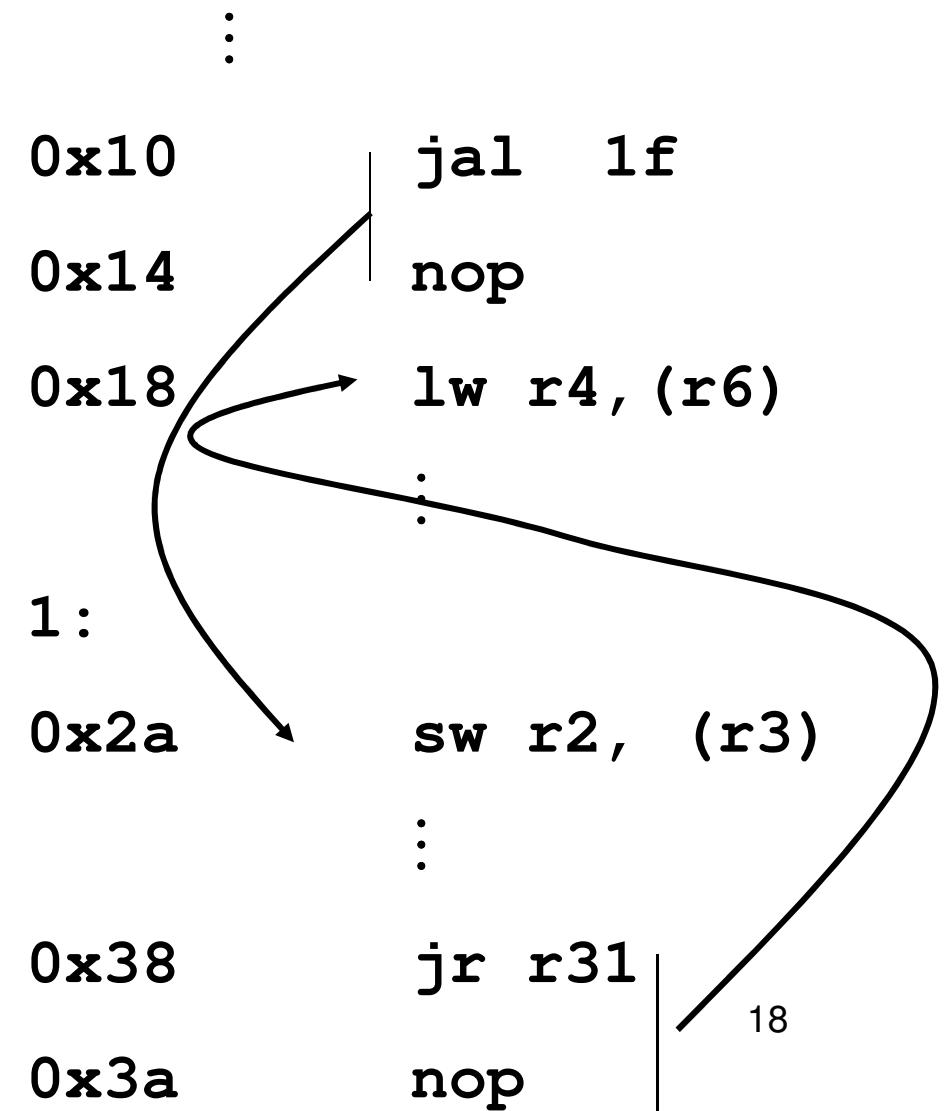

# Branching and Jumping

- Branching and jumping have a *branch delay slot*
    - The instruction following a branch or jump is always executed prior to destination
- |    |             |
|----|-------------|
|    | li r2, 1    |
|    | sw r0, (r3) |
|    | j 1f        |
|    | li r2, 2    |
|    | li r2, 3    |
| 1: | sw r2, (r3) |

# Jump and Link Instruction

- JAL is used to implement function calls
  - $r31 = PC+8$
- Return Address register (RA) is used to return from function call

# MIPS R3000

- RISC architecture – 5 stage pipeline

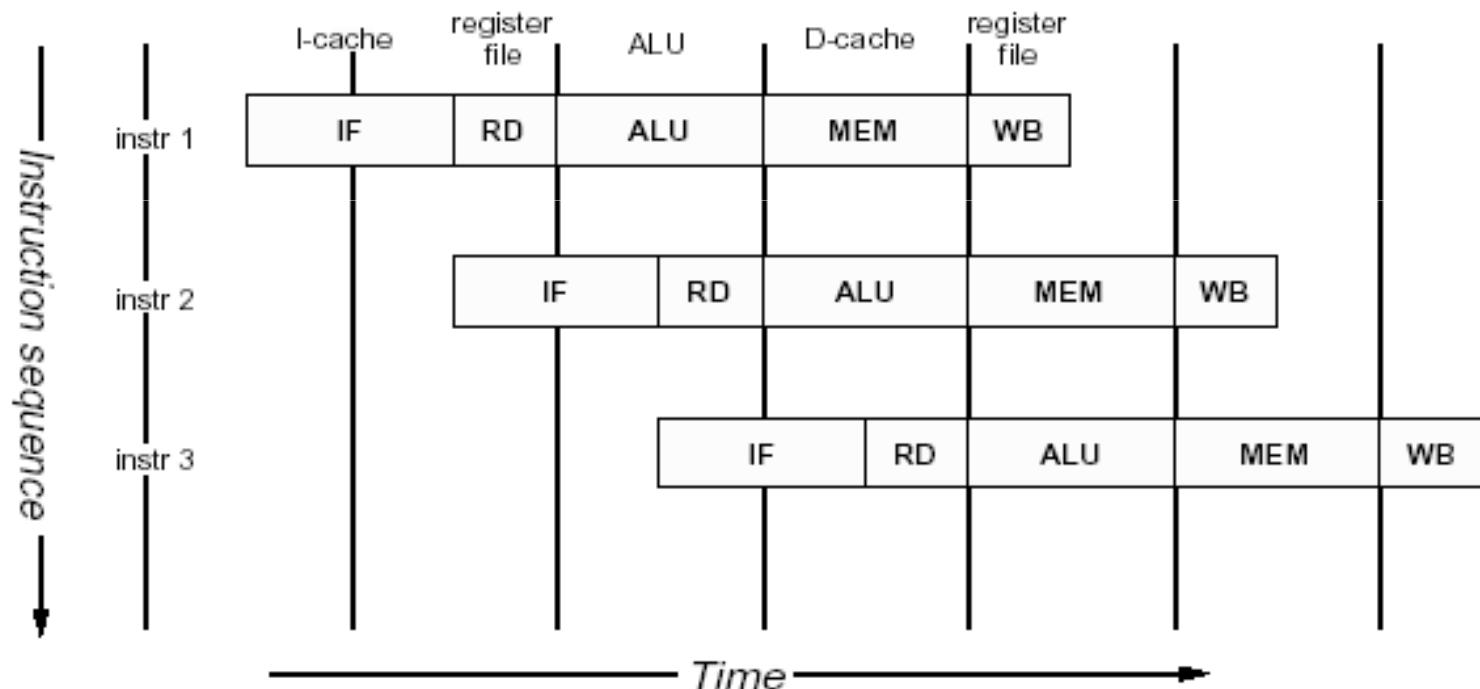

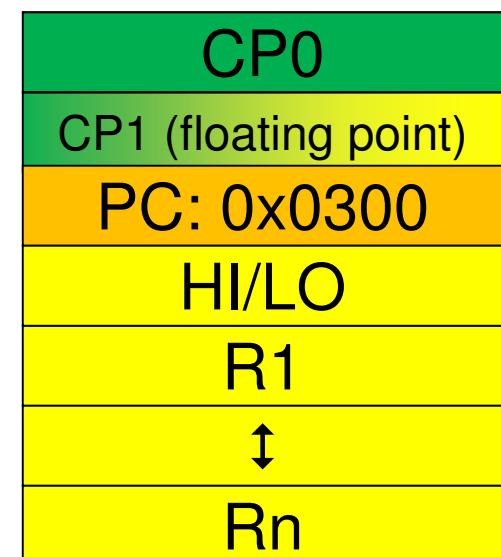

Figure 1.1. MIPS 5-stage pipeline

# Coprocessor 0

- The processor control registers are located in CP0
  - Exception/Interrupt management registers
  - Translation management registers
- CP0 is manipulated using mtc0 (move to) and mfc0 (move from) instructions
  - mtc0/mfc0 are only accessible in kernel mode.

# CP0 Registers

- Exception Management
  - c0\_cause
    - Cause of the recent exception
  - c0\_status
    - Current status of the CPU
  - c0\_epc
    - Address of the instruction that caused the exception
  - c0\_badvaddr
    - Address accessed that caused the exception
- Miscellaneous
  - c0\_prid
    - Processor Identifier
- Memory Management
  - c0\_index
  - c0\_random
  - c0\_entryhi
  - c0\_entrylo
  - c0\_context
- More about these later in course

# c0\_status

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CU3	CU2	CU1	CU0	0	RE	0	BEV	TS	PE	CM	PZ	SwC	IsC		
15					8	7	6	5	4	3	2	1	0		
	IM				0	KUo	IEo	KUp	IEp	KUc	IEc				

Figure 3.2. Fields in status register (SR)

- For practical purposes, you can ignore most bits
  - Green background is the focus

# c0\_status

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CU3	CU2	CU1	CU0	0	RE	0	BEV	TS	PE	CM	PZ	SwC	IsC		
15					8	7	6	5	4	3	2	1	0		
			IM			0	KUo	IEo	KUp	IEp	KUc	IEc			

Figure 3.2. Fields in status register (SR)

- **IM**
  - Individual interrupt mask bits
  - 6 external
  - 2 software
- **KU**
  - 0 = kernel
  - 1 = user mode
- **IE**
  - 0 = all interrupts masked
  - 1 = interrupts enable
    - Mask determined via IM bits
- c, p, o = current, previous, old

## c0\_cause

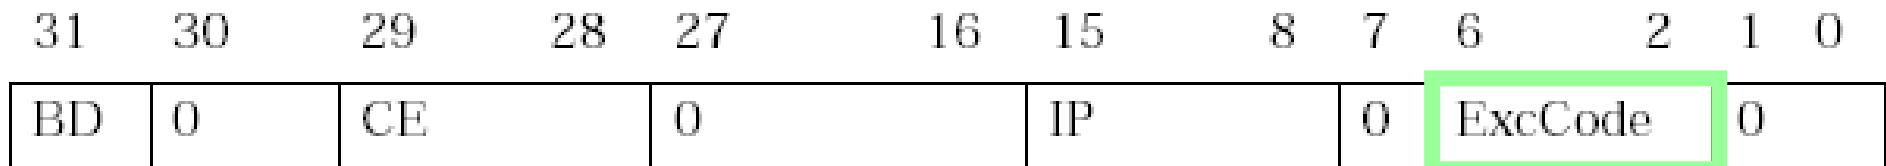

Figure 3.3. Fields in the Cause register

- **IP**
  - Interrupts pending
    - 8 bits indicating current state of interrupt lines
- **CE**
  - Coprocessor error
    - Attempt to access disabled Copro.
- **BD**
  - If set, the instruction that caused the exception was in a branch delay slot
- **ExcCode**
  - The code number of the exception taken

# Exception Codes

ExcCode Value	Mnemonic	Description
0	Int	Interrupt
1	Mod	"TLB modification"
2	TLBL	"TLB load/TLB store"
3	TLBS	
4	AdEL	Address error (on load/I-fetch or store respectively). Either an attempt to access outside kuseg when in user mode, or an attempt to read a word or half-word at a misaligned address.
5	AdES	

Table 3.2. ExcCode values: different kinds of exceptions

# Exception Codes

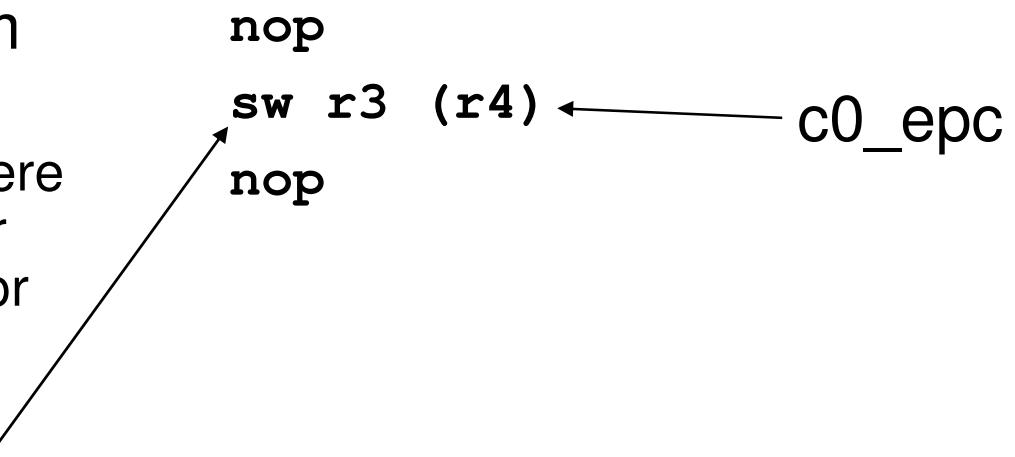

ExcCode Value	Mnemonic	Description
6	IBE	Bus error (instruction fetch or data load, respectively). External hardware has signalled an error of some kind; proper exception handling is system-dependent. The R30xx family CPUs can't take a bus error on a store; the write buffer would make such an exception "imprecise".
8	Syscall	Generated unconditionally by a <i>syscall</i> instruction.
9	Bp	Breakpoint - a <i>break</i> instruction.
10	RI	"reserved instruction"
11	CpU	"Co-Processor unusable"
12	Ov	"arithmetic overflow". Note that "unsigned" versions of instructions (e.g. <i>addu</i> ) never cause this exception.
13-31	-	reserved. Some are already defined for MIPS CPUs such as the R6000 and R4xxx

Table 3.2. ExcCode values: different kinds of exceptions

# c0\_epc

- The Exception Program Counter
  - Points to address of where to restart execution after handling the exception or interrupt
  - Example
    - Assume **sw r3, (r4)** causes a fault exception

Aside: We are ignore BD-bit in  
c0\_cause which is also used in  
reality on rare occasions.

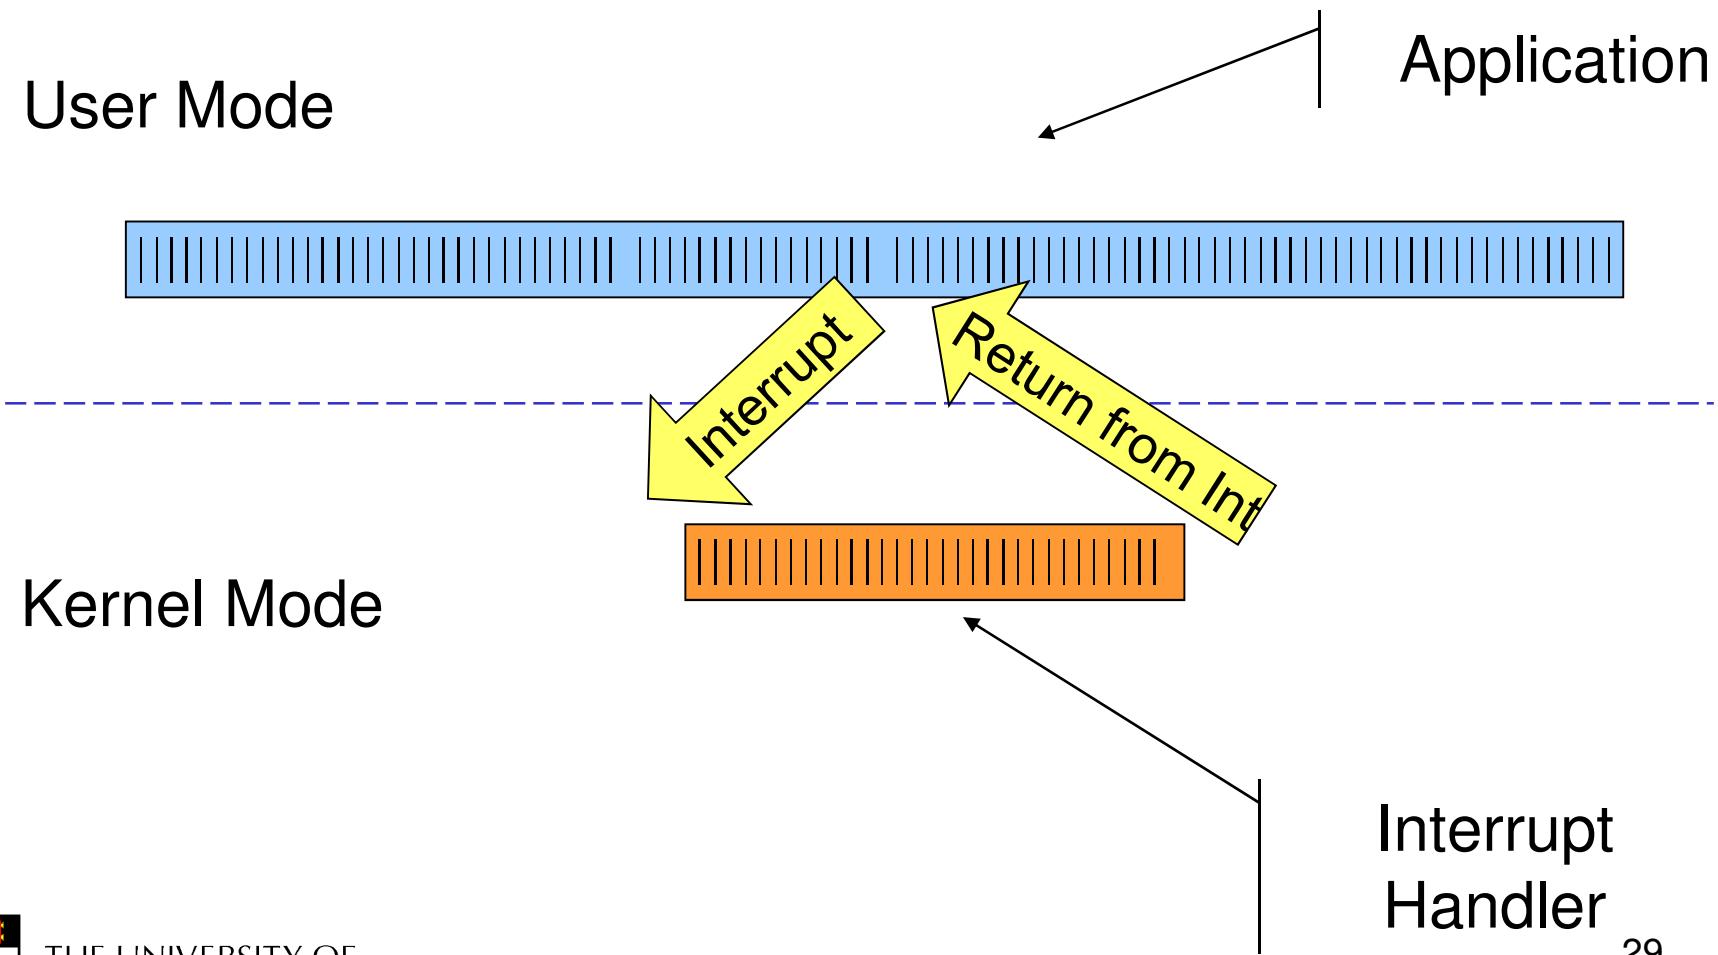

# Exception Vectors

Program address	“segment”	Physical Address	Description
0x8000 0000	kseg0	0x0000 0000	TLB miss on kuseg reference only.
0x8000 0080	kseg0	0x0000 0080	All other exceptions.
0xbfc0 0100	kseg1	0x1fc0 0100	Uncached alternative kuseg TLB miss entry point (used if SR bit BEV set).
0xbfc0 0180	kseg1	0x1fc0 0180	Uncached alternative for all other exceptions, used if SR bit BEV set).
0xbfc0 0000	kseg1	0x1fc0 0000	The “reset exception”.

Table 4.1. Reset and exception entry points (vectors) for R30xx family

# Function Stack Frames

- Each function call allocates a new stack frame for local variables, the return address, previous frame pointer etc.
  - Frame pointer: start of current stack frame
  - Stack pointer: end of current stack frame
- Example: assume f1() calls f2(), which calls f3().

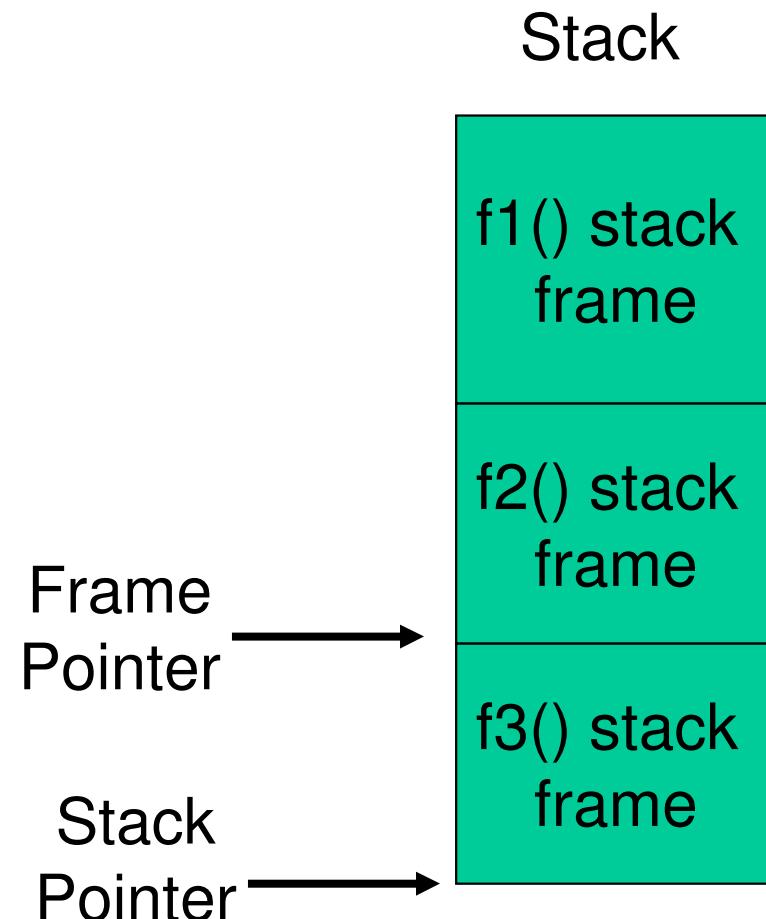

# Function Stack Frames

- Each function call allocates a new stack frame for local variables, the return address, previous frame pointer etc.
  - Frame pointer: start of current stack frame
  - Stack pointer: end of current stack frame
- Example: assume f1() calls f2(), which calls f3().

# Function Stack Frames

- Each function call allocates a new stack frame for local variables, the return address, previous frame pointer etc.
  - Frame pointer: start of current stack frame
  - Stack pointer: end of current stack frame
- Example: assume f1() calls f2(), which calls f3().

# Compiler Register Conventions

- Given 32 registers, which registers are used for
  - Local variables?
  - Argument passing?
  - Function call results?
  - Stack Pointer?

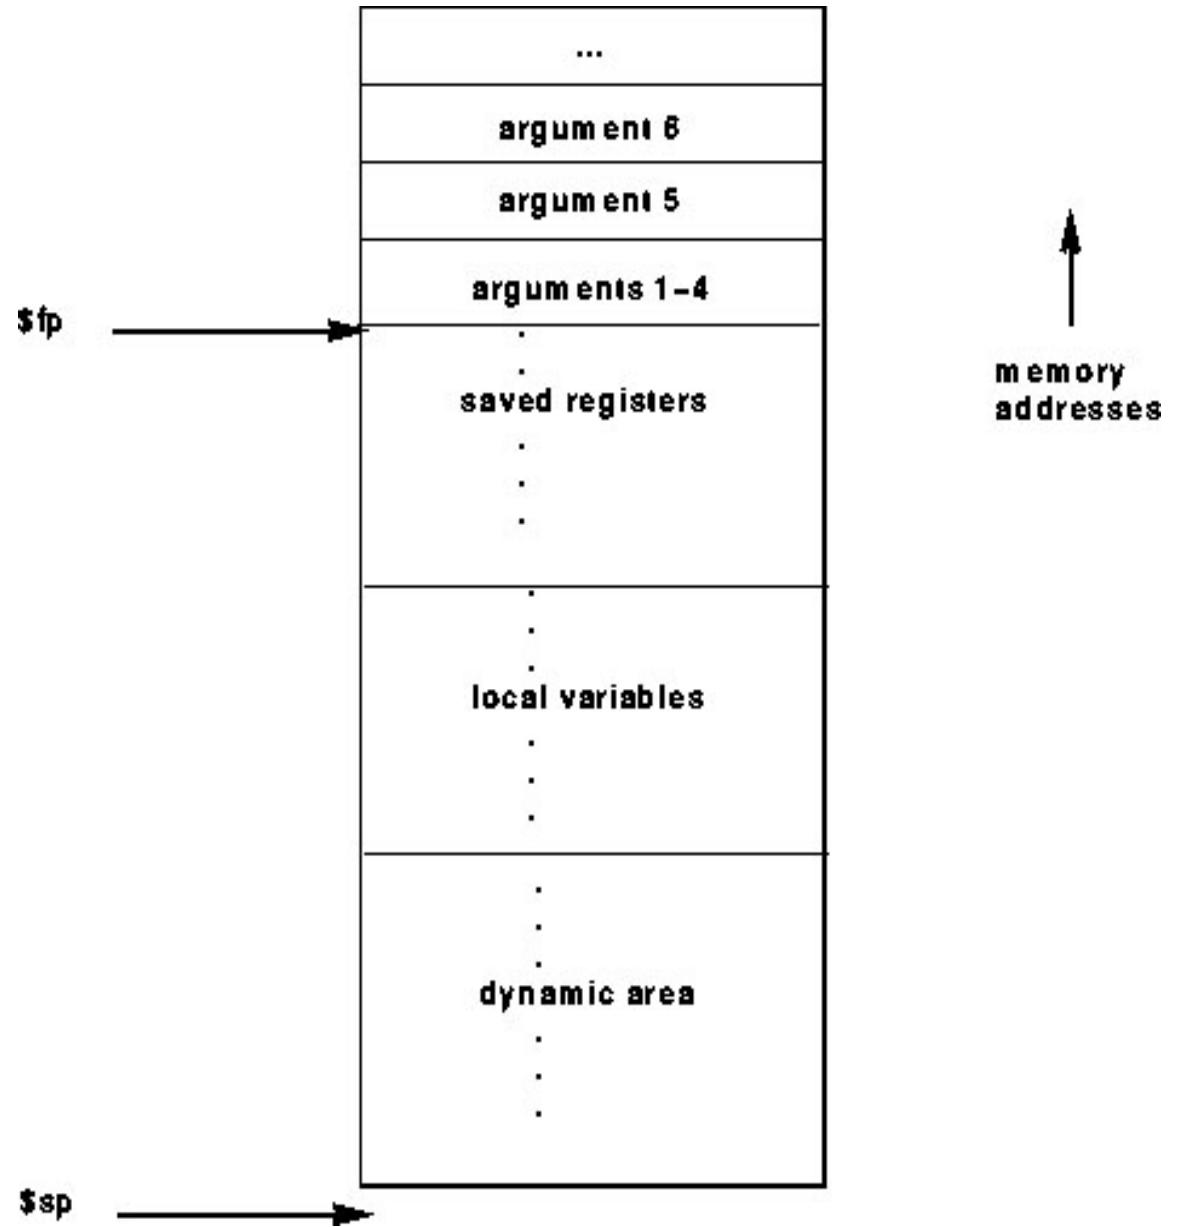

# Compiler Register Conventions

Reg No	Name	Used for
0	zero	Always returns 0
1	at	(assembler temporary) Reserved for use by assembler
2-3	v0-v1	Value (except FP) returned by subroutine
4-7	a0-a3	(arguments) First four parameters for a subroutine
8-15	t0-t7	(temporaries) subroutines may use without saving
24-25	t8-t9	
16-23	s0-s7	Subroutine “register variables”; a subroutine which will write one of these must save the old value and restore it before it exits, so the <i>calling</i> routine sees their values preserved.
26-27	k0-k1	Reserved for use by interrupt/trap handler - may change under your feet
28	gp	global pointer - some runtime systems maintain this to give easy access to (some) “static” or “extern” variables.
29	sp	stack pointer
30	s8/fp	9th register variable. Subroutines which need one can use this as a “frame pointer”.
31	ra	Return address for subroutine

# Stack Frame

- MIPS calling convention for gcc
  - Args 1-4 have space reserved for them

# Example Code

```
main ()                                int sixargs(int a, int b,  
{                                         int c, int d, int e,  
    int i;                               int f)  
  
    i =                                     return a + b + c + d  
    sixargs(1,2,3,4,5,6);                  + e + f;  
}
```

# System Calls

Continued

THE UNIVERSITY OF  
NEW SOUTH WALES

# User and Kernel Execution

- Simplistically, execution state consists of
  - Registers, processor mode, PC, SP
- User applications and the kernel have their own execution state.
- System call mechanism safely transfers from user execution to kernel execution and back.

# System Call Mechanism in Principle

- Processor mode
  - Switched from user-mode to kernel-mode
    - Switched back when returning to user mode
- SP
  - User-level SP is saved and a kernel SP is initialised
    - User-level SP restored when returning to user-mode
- PC
  - User-level PC is saved and PC set to kernel entry point
    - User-level PC restored when returning to user-level
  - Kernel entry via the designated entry point must be strictly enforced

# System Call Mechanism in Principle

- Registers
  - Set at user-level to indicate system call type and its arguments
    - A convention between applications and the kernel
  - Some registers are preserved at user-level or kernel-level in order to restart user-level execution
    - Depends on language calling convention etc.
  - Result of system call placed in registers when returning to user-level
    - Another convention

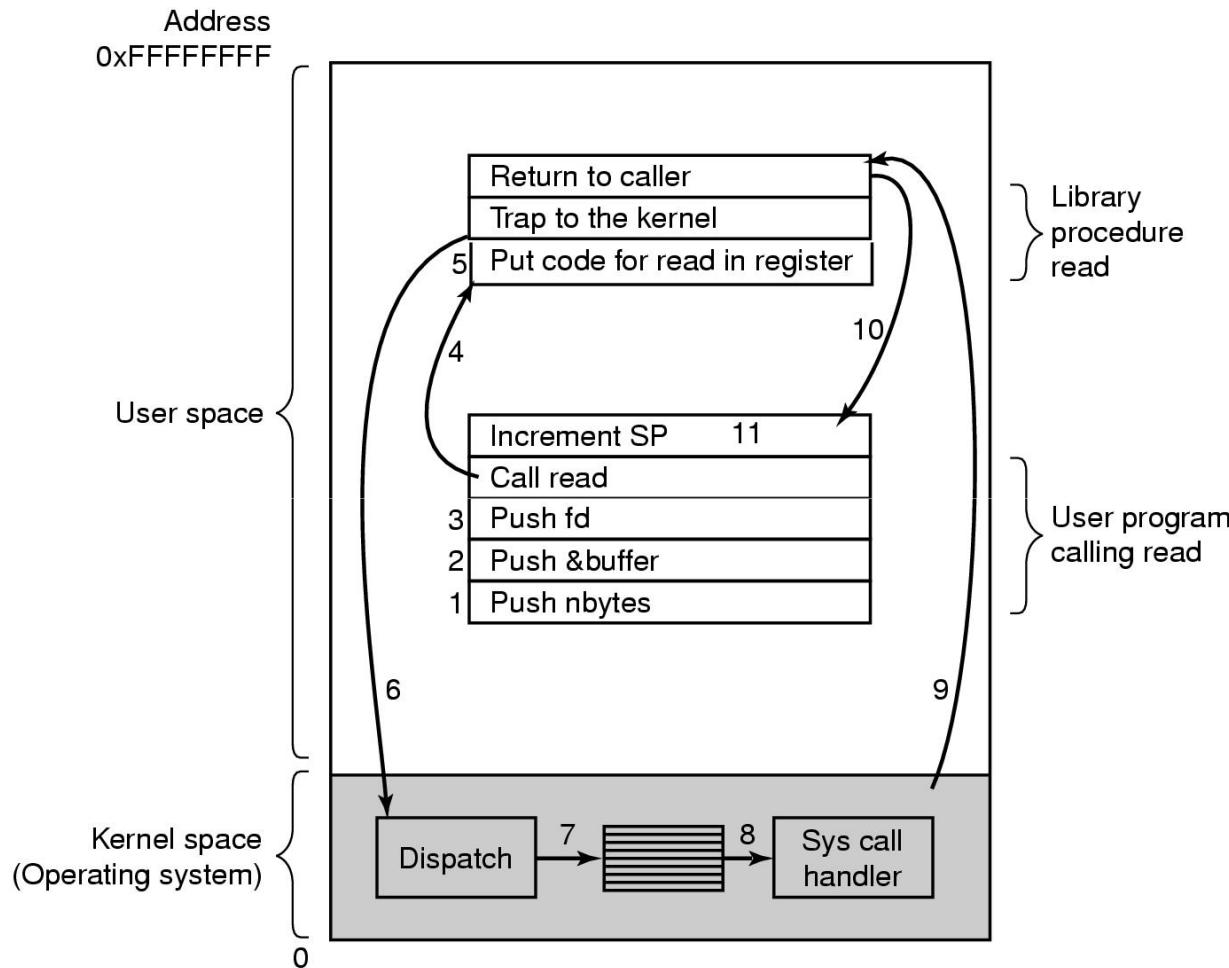

# Why do we need system calls?

- Why not simply jump into the kernel via a function call????
  - Function calls do not
    - Change from user to kernel mode
      - and eventually back again
    - Restrict possible entry points to secure locations

# Steps in Making a System Call

There are 11 steps in making the system call  
read (fd, buffer, nbytes)

# MIPS System Calls

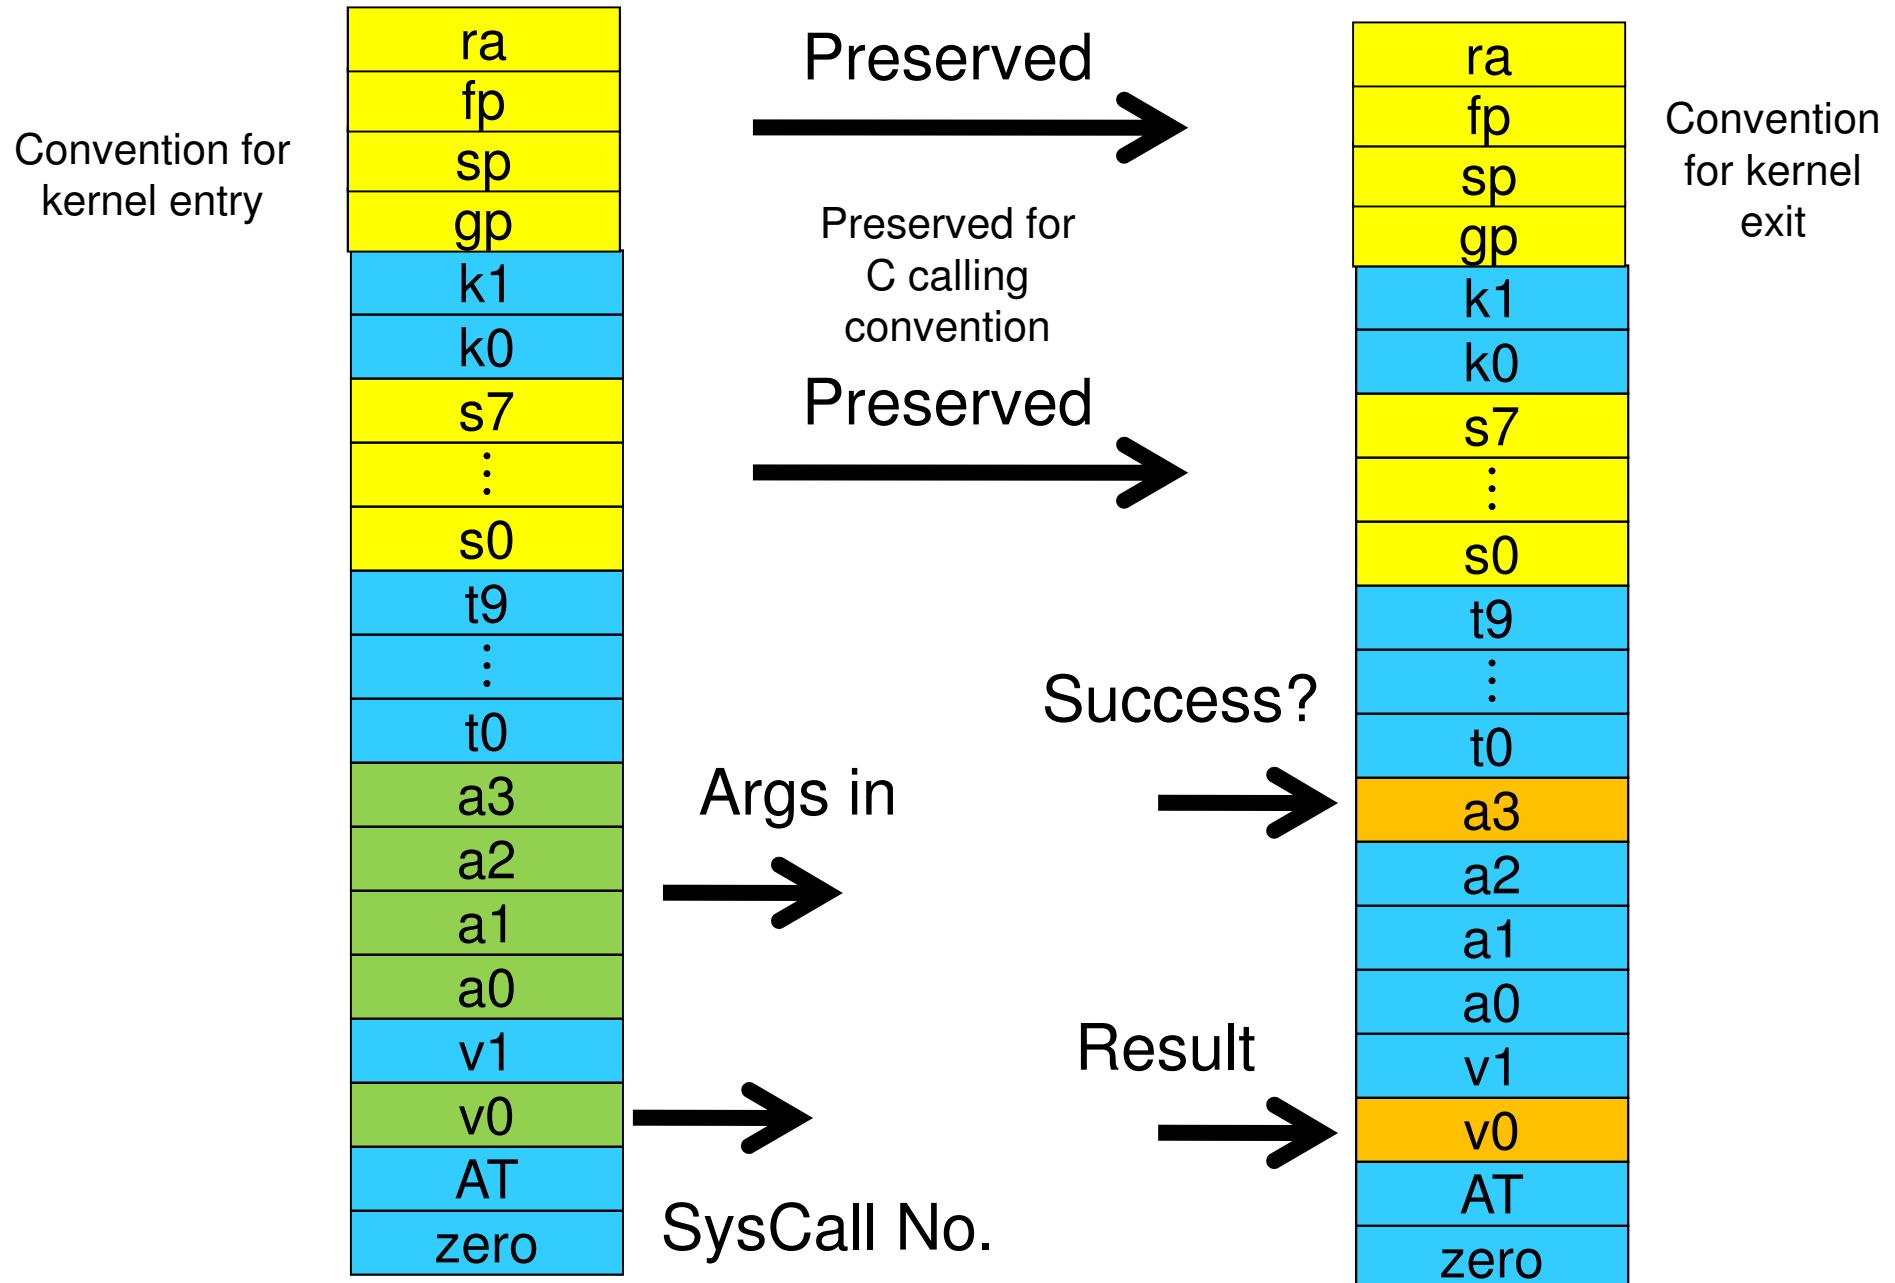

- System calls are invoked via a *syscall* instruction.
  - The *syscall* instruction causes an exception and transfers control to the general exception handler
  - A convention (an agreement between the kernel and applications) is required as to how user-level software indicates
    - Which system call is required
    - Where its arguments are
    - Where the result should go

# OS/161 Systems Calls

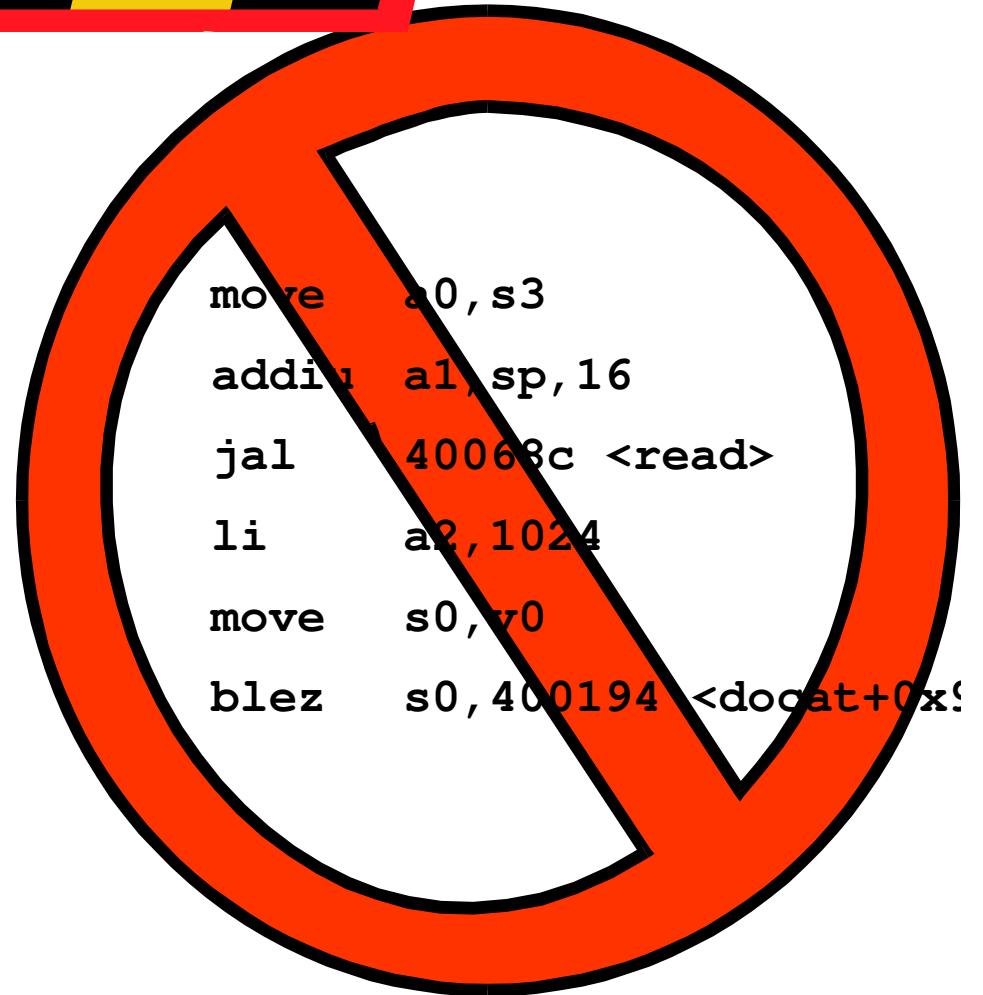

- OS/161 uses the following conventions
  - Arguments are passed and returned via the normal C function calling convention
  - Additionally
    - Reg v0 contains the system call number
    - On return, reg a3 contains
      - 0: if success, v0 contains successful result
      - not 0: if failure, v0 has the errno.
        - » v0 stored in errno
        - » -1 returned in v0

# CAUTION

- Seriously low-level code follows
- This code is not for the faint hearted

# User-Level System Call Walk Through – Calling read()

```
int read(int filehandle, void *buffer, size_t size)
```

- Three arguments, one return value
- Code fragment calling the read function

400124:	02602021	move a0, s3
400128:	27a50010	addiu a1, sp, 16
40012c:	0c1001a3	jal 40068c <read>
400130:	24060400	li a2, 1024
400134:	00408021	move s0, v0
400138:	1a000016	blez s0, 400194 <docat+0x94>

- Args are loaded, return value is tested

# Inside the read() syscall function

## part 1

0040068c <read>:

```
40068c: 08100190    j      400640 <__syscall>
400690: 24020005    li      v0, 5
```

- Appropriate registers are preserved
  - Arguments (a0-a3), return address (ra), etc.
- The syscall number (5) is loaded into v0
- Jump (not jump and link) to the common syscall routine

# The read() syscall function

## part 2

Generate a syscall exception

Return to location  
after where read()  
was called

# Summary

- From the caller's perspective, the read() system call behaves like a normal function call
  - It preserves the calling convention of the language
- However, the actual function implements its own convention by agreement with the kernel
  - Our OS/161 example assumes the kernel preserves appropriate registers(s0-s8, sp, gp, ra).
- Most languages have similar *support libraries* that interface with the operating system.

# System Calls - Kernel Side

- Things left to do
  - Change to kernel stack
  - Preserve registers by saving to memory (the stack)
  - Leave saved registers somewhere accessible to
    - Read arguments
    - Store return values
  - Do the “read()”
  - Restore registers
  - Switch back to user stack
  - Return to application

```

exception:
    move k1, sp          /* Save previous stack pointer in k1 */
    mfc0 k0, c0_status   /* Get status register */
    andi k0, k0, CST_LW  /* Check the we-were-in-user-mode bit */
    beq k0, $0, 1f /* If clear, from kernel, already have stack */
    nop               /* delay slot */

    /* Coming from user mode - save stack pointer into sp */
    la k0, curkstack
    lw sp, 0(k0)
    nop

1:
    mfc0 k0, c0_cause   /* Note cause */
    j common_exception
    nop

```

Note k0, k1  
registers  
available for  
kernel use

exception:

```
move k1, sp           /* Save previous stack pointer in k1 */
mfc0 k0, c0_status   /* Get status register */
andi k0, k0, CST_Kup /* Check the we-were-in-user-mode bit */
beq k0, $0, 1f /* If clear, from kernel, already have stack */
nop               /* delay slot */

/* Coming from user mode - load kernel stack into sp */
la k0, curkstack    /* get address of "curkstack" */
lw sp, 0(k0)         /* get its value */
nop               /* delay slot for the load */

1:
mfc0 k0, c0_cause   /* Now, load the exception cause. */
j common_exception   /* Skip to common code */
nop               /* delay slot */
```

```
common_exception:

/*
 * At this point:
 *     Interrupts are off. (The processor did this for us.)
 *     k0 contains the exception cause value.
 *     k1 contains the old stack pointer.
 *     sp points into the kernel stack.
 *     All other registers are untouched.
 */

/*
 * Allocate stack space for 37 words to hold the trap frame,
 * plus four more words for a minimal argument block.
 */
addi sp, sp, -164
```

```

/* The order here must match mips/include/trapframe.h. */

sw ra, 160(sp)      /* dummy for gdb */
sw s8, 156(sp)      /* save s8 */
sw sp, 152(sp)      /* dummy for gdb */
sw gp, 148(sp)      /* save gp */
sw k1, 144(sp)      /* dummy for gdb */
sw k0, 140(sp)      /* dummy for gdb */

sw k1, 152(sp)      /* real saved sp */
nop                  /* delay slot for store */

mfc0 k1, c0_epc     /* Copr.0 reg 13 == PC for
sw k1, 160(sp)      /* real saved PC */

```

These six stores are a “hack” to avoid confusing GDB  
 You can ignore the details of why and how

```
/* The order here must match mips/include/trapframe.h. */

sw ra, 160(sp)      /* dummy for gdb */
sw s8, 156(sp)      /* save s8 */
sw sp, 152(sp)      /* dummy for gdb */
sw gp, 148(sp)      /* save gp */
sw k1, 144(sp)      /* dummy for gdb */
sw k0, 140(sp)      /* dummy for gdb */

sw k1, 152(sp)      /* real saved sp */
nop                 /* delay slot for store */

mfco k1, c0_epc     /* Copr.0 reg 13 == PC for exception */
sw k1, 160(sp)      /* real saved PC */
```

The real work starts  
here

```
sw t9, 136(sp)
sw t8, 132(sp)
sw s7, 128(sp)
sw s6, 124(sp)
sw s5, 120(sp)
sw s4, 116(sp)
sw s3, 112(sp)
sw s2, 108(sp)
sw s1, 104(sp)
sw s0, 100(sp)
sw t7, 96(sp)
sw t6, 92(sp)
sw t5, 88(sp)
sw t4, 84(sp)
sw t3, 80(sp)
sw t2, 76(sp)
sw t1, 72(sp)
sw t0, 68(sp)
sw a3, 64(sp)
sw a2, 60(sp)
sw a1, 56(sp)
sw a0, 52(sp)
sw v1, 48(sp)
sw v0, 44(sp)
sw AT, 40(sp)
sw ra, 36(sp)
```

Save all the registers  
on the kernel stack

```
/*
 * Save special registers.
 */
mfhi t0
mflo t1
sw t0, 32(sp)
sw t1, 28(sp)
```

We can now use the other registers (t0, t1) that we have preserved on the stack

```
/*
 * Save remaining exception context information.
 */
```

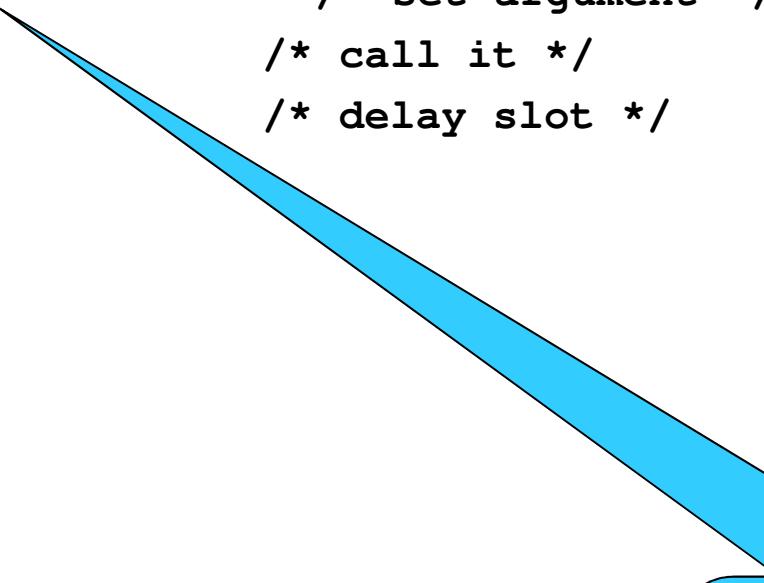

```
sw k0, 24(sp)          /* k0 was loaded with cause earlier */
mfc0 t1, c0_status     /* Copr.0 reg 11 == status */
sw t1, 20(sp)
mfc0 t2, c0_vaddr      /* Copr.0 reg 8 == faulting vaddr */
sw t2, 16(sp)
```

```
/*
 * Pretend to save $0 for gdb's benefit.
 */
sw $0, 12(sp)
```

```
/*
 * Prepare to call mips_trap(struct trapframe *)
 */

addiu a0, sp, 16          /* set argument */
jal mips_trap             /* call it */
nop                      /* delay slot */
```

Create a pointer to the base of the saved registers and state in the first argument register

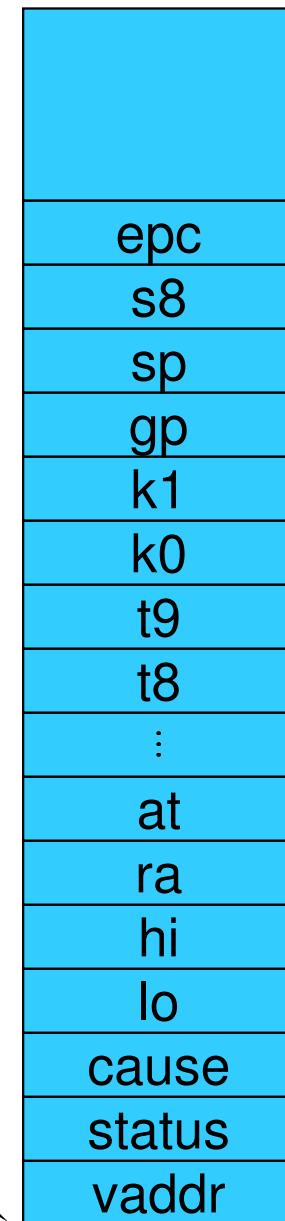

```

struct trapframe {
    u_int32_t tf_vaddr;          /* vaddr register */
    u_int32_t tf_status;         /* status register */
    u_int32_t tf_cause;          /* cause register */
    u_int32_t tf_lo;
    u_int32_t tf_hi;
    u_int32_t tf_ra; /* Saved register 31 */
    u_int32_t tf_at; /* Saved register 1 (AT) */
    u_int32_t tf_v0; /* Saved register 2 (v0) */
    u_int32_t tf_v1; /* etc. */
    u_int32_t tf_a0;
    u_int32_t tf_a1;
    u_int32_t tf_a2;
    u_int32_t tf_a3;
    u_int32_t tf_t0;
    :
    u_int32_t tf_t7;
    u_int32_t tf_s0;
    :
    u_int32_t tf_s7;
    u_int32_t tf_t8;
    u_int32_t tf_t9;
    u_int32_t tf_k0; /* dummy (see exception.S comment) */
    u_int32_t tf_k1; /* dummy */
    u_int32_t tf_gp;
    u_int32_t tf_sp;
    u_int32_t tf_s8;
    u_int32_t tf_epc;           /* coprocessor 0 epc register
}

```

By creating a pointer to here of type `struct trapframe *`, we can access the user's saved registers as normal variables within 'C'

## Kernel Stack

# Now we arrive in the ‘C’ kernel

```
/*
 * General trap (exception) handling function for mips.
 * This is called by the assembly-language exception handler once
 * the trapframe has been set up.
 */
void
mips_trap(struct trapframe *tf)
{
    u_int32_t code, isutlb, iskern;
    int savespl;

    /* The trap frame is supposed to be 37 registers long. */
    assert(sizeof(struct trapframe)==(37*4));

    /* Save the value of curspl, which belongs to the old context. */
    savespl = curspl;

    /* Right now, interrupts should be off. */
    curspl = SPL_HIGH;
```

# What happens next?

- The kernel deals with whatever caused the exception
  - Syscall
  - Interrupt
  - Page fault
  - It potentially modifies the *trapframe*, etc
    - E.g., Store return code in v0, zero in a3
- ‘mips\_trap’ eventually returns

```

exception_return:

/*      16(sp)          no need to restore tf_vaddr */
lw t0, 20(sp)           /* load status register value into t0 */
