if !HaveFJCVTZSExt() then UnallocatedEncoding();

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(64) fltval;
bits(32) intval;
fltval = V[n];
intval = FPToFixedJS(fltval, FPCR, TRUE);
X[d] = ZeroExtend(intval<31:0>, 64);
C7.2.93  FMADD

Floating-point fused Multiply-Add (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, adds the product to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Half-precision variant
Applies when type == 11.

FMADD <Hd>, <Hn>, <Hm>, <Ha>

### Single-precision variant
Applies when type == 00.

FMADD <Sd>, <Sn>, <Sm>, <Sa>

### Double-precision variant
Applies when type == 01.

FMADD <Dd>, <Dn>, <Dm>, <Da>

#### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer a = UInt(Ra);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
  when '00' datasize = 32;
  when '01' datasize = 64;
  when '10' UnallocatedEncoding();
  when '11'
    if HaveFP16Ext() then
      datasize = 16;
    else
      UnallocatedEncoding();
```

#### Assembler symbols

- `<Dd>`  Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Dn>`  Is the 64-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.
Is the 64-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.

Is the 64-bit name of the third SIMD&FP source register holding the addend, encoded in the "Ra" field.

Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

Is the 16-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.

Is the 16-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.

Is the 16-bit name of the third SIMD&FP source register holding the addend, encoded in the "Ra" field.

Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

Is the 32-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.

Is the 32-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.

Is the 32-bit name of the third SIMD&FP source register holding the addend, encoded in the "Ra" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand = V[a];
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPMulAdd(operand, operand1, operand2, FPCR);

V[d] = result;
```
C7.2.94   FMAX (vector)

Floating-point Maximum (vector). This instruction compares corresponding vector elements in the two source
SIMD&FP registers, places the larger of each of the two floating-point values into a vector, and writes the vector to
the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

2H when sz = 0
The encoding sz = 1 is reserved.

For the single-precision and double-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:
2S when sz = 0
2D when sz = 1

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_FMAXNUM, operand, esize);
C7.2.99 FMAXNMP (vector)

Floating-point Maximum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Rn   Rd

Half-precision variant

FMAXNMV <V><d>, <Vn>.<T>

Decode for this encoding

if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;

Single-precision and double-precision

Half-precision and double-precision variant

FMAXNMV <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q != '01' then ReservedValue();   // .4S only

integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
**Assembler symbols**

- `<V>` For the half-precision variant: is the destination width specifier, H.
  For the single-precision and double-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:
  - `S` when `sz = 0`
  The encoding `sz = 1` is reserved.

- `<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- `<n>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<T>` For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - `4H` when `Q = 0`
  - `8H` when `Q = 1`

  For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:
  - `4S` when `Q = 1`, `sz = 0`

  The following encodings are reserved:
  - `Q = 0`, `sz = x`.
  - `Q = 1`, `sz = 1`.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_FMAXNUM, operand, esize);
```
C7.2.101 FMAXP (scalar)

Floating-point Maximum of Pair of elements (scalar). This instruction compares two vector elements in the source SIMD&FP register and writes the largest of the floating-point values as a scalar to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMAXP <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32;
integer datasize = 64;

Assembler symbols

<V>

For the half-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:

H when sz = 0

The encoding sz = 1 is reserved.
For the single-precision and double-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:

- S when \( sz = 0 \)
- D when \( sz = 1 \)

\(<d>\) Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

\(<\text{Vn}>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<\text{T}>\) For the half-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:

- 2H when \( sz = 0 \)
- The encoding \( sz = 1 \) is reserved.

For the single-precision and double-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:

- 2S when \( sz = 0 \)
- 2D when \( sz = 1 \)

**Operation for all encodings**

```c
CheckFPAvSIMDEnabled64();
bits(datasize) operand = \text{V}[n];
\text{V}[d] = \text{Reduce}(ReduceOp\_FMAX, operand, esize);
```
C7.2.102  FMAXP (vector)

Floating-point Maximum Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, writes the larger of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
result = FPMinNum(operand1, operand2, FPCR);
V[d] = result;
```
C7.2.108   FMINNMP (scalar)

Floating-point Minimum Number of Pair of elements (scalar). This instruction compares two vector elements in the source SIMD&FP register and writes the smallest of the floating-point values as a scalar to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<V> For the half-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:

H  when sz = 0

The encoding sz = 1 is reserved.
For the single-precision and double-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:

- \( S \) when \( sz = 0 \)
- \( D \) when \( sz = 1 \)

\(<d>\) Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

\(<vn>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<t>\) For the half-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:

- \( 2H \) when \( sz = 0 \)
- The encoding \( sz = 1 \) is reserved.

For the single-precision and double-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:

- \( 2S \) when \( sz = 0 \)
- \( 2D \) when \( sz = 1 \)

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_FMINNUM, operand, esize);
```
C7.2.109  **FMINNMP (vector)**

Floating-point Minimum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of floating-point values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
S when sz = 0
D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector, half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
4H when Q = 0
8H when Q = 1

For the vector, single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:
2S when Q = 0, sz = 0
4S when Q = 1, sz = 0
2D when Q = 1, sz = 1

The encoding Q = 0, sz = 1 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> For the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rn" field.
For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

<Ts> Is an element size specifier, encoded in the "sz" field. It can have the following values:
S when sz = 0
D when sz = 1

<index> For the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.
For the single-precision and double-precision variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:
H:L when sz = 0, L = x
H when sz = 1, L = 0
The encoding sz = 1, L = 1 is reserved.

C7.2.115  FMLA (vector)

Floating-point fused Multiply-Add to accumulator (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, adds the product to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- \(4H\) when \(Q = 0\)
- \(8H\) when \(Q = 1\)

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- \(2S\) when \(sz = 0, Q = 0\)
- \(4S\) when \(sz = 0, Q = 1\)
- \(2D\) when \(sz = 1, Q = 1\)

The encoding \(sz = 1, Q = 0\) is reserved.

\(<V_n>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<V_m>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

\[
\text{CheckFPAdvSIMDEnabled64();}
\]

\[
\text{bits}(\text{datasize}) \text{ operand1} = V[n];
\]

\[

\]
C7.2.120  FMLSL, FMLSL2 (by element)

Floating-point fused Multiply-Subtract Long from accumulator (by element). This instruction multiplies the negated vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

From ARMv8.2, this is an optional instruction.

**Note**

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

V[d] = result;
```
### C7.2.121 FMLSL, FMLSL2 (vector)

Floating-point fused Multiply-Subtract Long from accumulator (vector). This instruction negates the values in the vector of one SIMD&FP register, multiplies these with the corresponding values in another vector, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

From ARMv8.2, this is an **optional** instruction.

Operation

CheckFPAdvSIMDEnabled64();

V[d] = imm;
### C7.2.126 FMSUB

Floating-point Fused Multiply-Subtract (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, adds that to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Half-precision variant

Applies when `type` == 11.

FMSUB <Hd>, <Hn>, <Hm>, <Ha>

#### Single-precision variant

Applies when `type` == 00.

FMSUB <Sd>, <Sn>, <Sm>, <Sa>

#### Double-precision variant

Applies when `type` == 01.

FMSUB <Dd>, <Dn>, <Dm>, <Da>

#### Decode for all variants of this encoding

```plaintext
integer d = UInt(Rd);
integer a = UInt(Ra);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
  when '00' datasize = 32;
  when '01' datasize = 64;
  when '10' UnallocatedEncoding();
  when '11'
    if HaveFP16Ext() then
      datasize = 16;
    else
      UnallocatedEncoding();
```

#### Assembler symbols

- `<Dd>` is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Dn>` is the 64-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.
<Dm>  Is the 64-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.

<Da>  Is the 64-bit name of the third SIMD&FP source register holding the minuend, encoded in the "Ra" field.

<Hd>  Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn>  Is the 16-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.

<Hm>  Is the 16-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.

<Ha>  Is the 16-bit name of the third SIMD&FP source register holding the minuend, encoded in the "Ra" field.

<Sd>  Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn>  Is the 32-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.

<Sm>  Is the 32-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.

<Sa>  Is the 32-bit name of the third SIMD&FP source register holding the minuend, encoded in the "Ra" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operanda = V[a];
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

operand1 = FPNeg(operand1);
result = FPMulAdd(operanda, operand1, operand2, FPCR);
V[d] = result;
```

C7 A64 Advanced SIMD and Floating-point Instruction Descriptions
C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions
C7.2.127   FMUL (by element)

Floating-point Multiply (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPSCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar, half-precision

ARMv8.2

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean mulx_op = (U == '1');

**Assembler symbols**

<
**Hd**
Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<
**Hn**
Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<
**V**
Is a width specifier, encoded in the "sz" field. It can have the following values:

S when sz = 0
D when sz = 1

<
**d**
Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<
**n**
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<
**Vd**
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<
**T**
For the vector, half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0
8H when Q = 1

For the vector, single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:

2S when Q = 0, sz = 0
4S when Q = 1, sz = 0
2D when Q = 1, sz = 1

The encoding Q = 0, sz = 1 is reserved.

<
**Vn**
Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<
**hm**
For the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rm" field.

For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.

<
**Ts**
Is an element size specifier, encoded in the "sz" field. It can have the following values:

S when sz = 0
D when sz = 1

<
**index**
For the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.

For the single-precision and double-precision variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:

H:L when sz = 0, L = x
H when sz = 1, L = 0

The encoding sz = 1, L = 1 is reserved.
Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2 = Elem[operand2, index, esize];

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    if mulx_op then
        Elem[result, e, esize] = FPMulX(element1, element2, FPCR);
    else
        Elem[result, e, esize] = FPMul(element1, element2, FPCR);

V[d] = result;
C7.2.128  FMUL (vector)

Floating-point Multiply (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, places the result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision

ARMv8.2

| 0 | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 1 | Rm | 0 | 0 | 1 | 1 | Rd |

Half-precision variant

FMUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;

Single-precision and double-precision

| 0 | 0 | 1 | 1 | 1 | 0 | 0 | sz | 1 | Rm | 1 | 1 | 0 | 1 | 1 | Rd |

Single-precision and double-precision variant

FMUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 4H when Q = 0
- 8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- 2S when sz = 0, Q = 0
- 4S when sz = 0, Q = 1
- 2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = FPMul(element1, element2, FPCR);

V[d] = result;
```
C7.2.129  **FMUL (scalar)**

Floating-point Multiply (scalar). This instruction multiplies the floating-point values of the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Half-precision variant

Applies when type == 11.

**FMUL <Hd>, <Hn>, <Hm>**

### Single-precision variant

Applies when type == 00.

**FMUL <Sd>, <Sn>, <Sm>**

### Double-precision variant

Applies when type == 01.

**FMUL <Dd>, <Dn>, <Dm>**

### Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
  when '00' datasize = 32;
  when '01' datasize = 64;
  when '10' UnallocatedEncoding();
  when '11'
    if HaveFP16Ext() then
      datasize = 16;
    else
      UnallocatedEncoding();
```

### Assembler symbols

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Hn>` Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPMul(operand1, operand2, FPCR);

V[d] = result;
```
C7.2.130  FMULX (by element)

Floating-point Multiply extended (by element). This instruction multiplies the floating-point values in the vector elements in the first source SIMD&FP register by the specified floating-point value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If one value is zero and the other value is infinite, the result is 2.0. In this case, the result is negative if only one of the values is negative, otherwise the result is positive.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
  S when sz = 0
  D when sz = 1
<db> Is the number of the SIMD&FP destination register, in the "Rd" field.
<nb> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<mb> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
<Vdb> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 4H when Q = 0
- 8H when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- 2S when sz = 0, Q = 0
- 4S when sz = 0, Q = 1
- 2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = FPMulX(element1, element2, FPCR);
V[d] = result;
```
C7.2.132 FNEG (vector)

Floating-point Negate (vector). This instruction negates the value of each vector element in the source SIMD&FP register, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    Elem[result, e, esize] = FPRecipStepFused(element1, element2);

V[d] = result;
```
C7.2.139 FRECPX

Floating-point Reciprocal exponent (scalar). This instruction finds an approximate reciprocal exponent for each vector element in the source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Half-precision**

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
```

**Assembler symbols**

- `<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Hn>` Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<v> Is a width specifier, encoded in the "sz" field. It can have the following values:
S when sz = 0
D when sz = 1
<\> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<\> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
   element = Elem[operand, e, esize];
   Elem[result, e, esize] = FPRecpX(element, FPCR);

V[d] = result;
```
C7.2.140   FRINTA (vector)

Floating-point Round to Integral, to nearest with ties to Away (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.146   FRINTN (vector)

Floating-point Round to Integral, to nearest with ties to even (vector). This instruction rounds a vector of
floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the
Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and
a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

  when '111' rounding = FPRoundingMode(FPCR);

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - `4H` when Q = 0
  - `8H` when Q = 1

  For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
  - `2S` when sz = 0, Q = 0
  - `4S` when sz = 0, Q = 1
  - `2D` when sz = 1, Q = 1

  The encoding sz = 1, Q = 0 is reserved.
- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```plaintext
CheckFPAdvSIMDEnabled64();
operand = V[n];
result = bits(dataSize);
elements = bits(esize);
for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPRoundInt(element, FPCR, rounding, exact);

V[d] = result;
```
C7.2.147   FRINTN (scalar)

Floating-point Round to Integral, to nearest with ties to even (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:

S when sz = 0
D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0
8H when Q = 1
For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0
4S when sz = 0, Q = 1
2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPRSqrtEstimate(element, FPCR);

V[d] = result;
```
C7.2.155   FRSQRTS

Floating-point Reciprocal Square Root Step. This instruction multiplies corresponding floating-point values in the vectors of the two source SIMD&FP registers, subtracts each of the products from 3.0, divides these results by 2.0, places the results into a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPSub(operand1, operand2, FPCR);
V[d] = result;
```
C7.2.160   **INS (element)**

Insert vector element from another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (element). The alias is always the preferred disassembly.

Advanced SIMD variant

INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

**Decode for this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer dst_index = UInt(imm5<4:size+1>);
integer src_index = UInt(imm4<size:3>);
integer idxdsize = if imm4<3> == '1' then 128 else 64;
// imm4<size-1:0> is IGNORED

integer esize = 8 << size;
```

**Assembler symbols**

`<Vd>`  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ts>`  Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- **B**  when imm5 = xxxx1
- **H**  when imm5 = xxx10
- **S**  when imm5 = xx100
- **D**  when imm5 = x1000

The encoding imm5 = x0000 is reserved.

`<index1>`  Is the destination element index encoded in the "imm5" field. It can have the following values:

- imm5<4:1>  when imm5 = xxxx1
- imm5<4:2>  when imm5 = xxx10
- imm5<4:3>  when imm5 = xx100
- imm5<4>    when imm5 = x1000

The encoding imm5 = x0000 is reserved.

`<Vn>`  Is the name of the SIMD&FP source register, encoded in the "Rn" field.
Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

- \( \text{imm4}^{3:0} \) when \( \text{imm5} = xxxx1 \)
- \( \text{imm4}^{3:1} \) when \( \text{imm5} = xxx10 \)
- \( \text{imm4}^{3:2} \) when \( \text{imm5} = xx100 \)
- \( \text{imm4}^{3} \) when \( \text{imm5} = x1000 \)

The encoding \( \text{imm5} = x0000 \) is reserved.

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(idxds) operand = V[n];
bits(128) result;

result = V[d];
Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
V[d] = result;
```
C7.2.161   INS (general)

Insert vector element from general-purpose register. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (from general). The alias is always the preferred disassembly.

```
| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 | 5 4 | 0 |
| 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | imm5 | 0 | 0 | 1 | 1 |
```

**Advanced SIMD variant**

INS <Vd>.<Ts>[<index>], <R><n>

**Decode for this encoding**

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();
integer index = UInt(imm5<4:size+1>);
integer esize = 8 << size;
```

**Assembler symbols**

- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ts>` is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - `B` when `imm5 = xxxx1`
  - `H` when `imm5 = xxx10`
  - `S` when `imm5 = xx100`
  - `D` when `imm5 = x1000`
  - The encoding `imm5 = x0000` is reserved.
- `<index>` is the element index encoded in the "imm5" field. It can have the following values:

  - `imm5<4:3>` when `imm5 = xx100`
  - `imm5<4>` when `imm5 = x1000`
  - The encoding `imm5 = x0000` is reserved.
- `<R>` is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:
  - `W` when `imm5 = xxxx1`
  - `W` when `imm5 = xxx10`
W when imm5 = xx100
X when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<\> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(128) result;

result = V[d];
Elem[result, index, esize] = element;
V[d] = result;
C7.2.162  LD1 (multiple structures)

Load multiple single-element structures to one, two, three, or four registers. This instruction loads multiple single-element structures from memory and writes the result to one, two, three, or four SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

m &= \text{U} \text{I} \text{n}t(Rm); \\
wback &= \text{TR}UE;
\end{align*}
\]

Assembler symbols
\(<Vt>\)
Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

\(<T>\)
Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- \( 8B \) when \( size = 00, Q = 0 \)
- \( 16B \) when \( size = 00, Q = 1 \)
- \( 4H \) when \( size = 01, Q = 0 \)
- \( 8H \) when \( size = 01, Q = 1 \)
- \( 2S \) when \( size = 10, Q = 0 \)
- \( 4S \) when \( size = 10, Q = 1 \)
- \( 1D \) when \( size = 11, Q = 0 \)
- \( 2D \) when \( size = 11, Q = 1 \)

\(<Vt2>\)
Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

\(<Vt3>\)
Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

\(<Vt4>\)
Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #8 when Q = 0
- #16 when Q = 1

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #16 when Q = 0
- #32 when Q = 1

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #24 when Q = 0
- #48 when Q = 1

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #32 when Q = 0
- #64 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```assembly
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = if Q == '1' then 128 else 64;

**Assembler symbols**

- \(<Vt>\) Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- \(<T>\) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
The encoding size = 11, Q = 0 is reserved.

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> Is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#16 when Q = 0
#32 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

**Shared decode for all encodings**

```c
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = if Q == '1' then 128 else 64;
integer esize = 8 << UInt(size);
integer elements = datasize DIV esize;

integer rpt;    // number of iterations
integer selem;    // structure elements

case opcode of
    when '0000' rpt = 1; selem = 4;    // LD/ST4 (4 registers)
    when '0010' rpt = 4; selem = 1;    // LD/ST1 (4 registers)
    when '0100' rpt = 1; selem = 3;    // LD/ST3 (3 registers)
    when '0110' rpt = 3; selem = 1;    // LD/ST1 (3 registers)
    when '0111' rpt = 1; selem = 1;    // LD/ST1 (1 register)
    when '1000' rpt = 2; selem = 1;    // LD/ST1 (2 registers)
    otherwise UnallocatedEncoding();

// .1D format only permitted with LD1 & ST1
if size:Q == '110' && selem != 1 then ReservedValue();
```

C7  A64 Advanced SIMD and Floating-point Instruction Descriptions

C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions

C7.2.166   LD2 (single structure)

Load single 2-element structure to one lane of two registers. This instruction loads a 2-element structure from
memory and writes the result to the corresponding elements of the two SIMD&FP registers without affecting the
other bits of the registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

No offset

LD2 { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>]

8-bit variant
Applies when opcode == 000.
LD2 { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>]

16-bit variant
Applies when opcode == 010 && size == x0.
LD2 { <Vt>.H, <Vt2>.H }[<index>], [<Xn|SP>]

32-bit variant
Applies when opcode == 100 && size == 00.
LD2 { <Vt>.S, <Vt2>.S }[<index>], [<Xn|SP>]

64-bit variant
Applies when opcode == 100 && S == 0 && size == 01.
LD2 { <Vt>.D, <Vt2>.D }[<index>], [<Xn|SP>]

Decode for all variants of this encoding

m & = \text{UInt}(Rm); \\
\text{wback} & = \text{TRUE};
\end{align*}
\]

Assembler symbols

\(<\langle Vt \rangle>\>
Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

\(<\langle Vt2 \rangle>\>
Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

\(<\langle Vt3 \rangle>\>
Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

\(<\langle index \rangle>\>
For the 8-bit variant: is the element index, encoded in "Q:S:size".
For the 16-bit variant: is the element index, encoded in "Q:S:size<1>".
For the 32-bit variant: is the element index, encoded in "Q:S".
For the 64-bit variant: is the element index, encoded in "Q".

\(<\langle Xn|SP \rangle>\>
Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

\(<\langle Xm \rangle>\>
Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

C7.2.174 LDNP (SIMD&FP)

Load Pair of SIMD&FP registers, with Non-temporal hint. This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point Non-temporal pair on page C3-178.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\]

**Assembler symbols**

\[
<\text{Bt}> \quad \text{Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.}
\]

\[
<\text{Dt}> \quad \text{Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.}
\]
<Rt>
Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Qt>
Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<St>
Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Xn|SP>
Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Sm>
When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm>
When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend>
For the 8-bit variant: is the index extend specifier, encoded in the "option" field. It can have the following values:
- **UXTW** when option = 010
- **SXTW** when option = 110
- **SXTX** when option = 111

For the 128-bit, 16-bit, 32-bit and 64-bit variant: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:
- **UXTW** when option = 010
- **LSL** when option = 011
- **SXTW** when option = 110
- **SXTX** when option = 111

<amount>
For the 8-bit variant: is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

For the 16-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
- #0 when S = 0
- #1 when S = 1

For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
- #0 when S = 0
- #2 when S = 1

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
- #0 when S = 0
- #3 when S = 1

For the 128-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
- #0 when S = 0
- #4 when S = 1
Shared decode for all encodings

        Elem[result, e, esize] = Elem[operand3, e, esize] + product;

V[d] = result;
C7.2.184 MOV (scalar)

Move vector element to scalar. This instruction duplicates the specified vector element in the SIMD&FP source register into a scalar, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the DUP (element) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (element).
- The description of DUP (element) gives the operational pseudocode for this instruction.

Scalar variant

MOV <V><d>, <Vn>.<T>[<index>]

is equivalent to

DUP <V><d>, <Vn>.<T>[<index>]

and is always the preferred disassembly.

Assembler symbols

<V> Is the destination width specifier, encoded in the "imm5" field. It can have the following values:
- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is the element width specifier, encoded in the "imm5" field. It can have the following values:
- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<index> Is the element index encoded in the "imm5" field. It can have the following values:
- imm5<4:1> when imm5 = xxxx1
- imm5<4:2> when imm5 = xxx10
- imm5<4:3> when imm5 = xx100
- imm5<4> when imm5 = x1000

The encoding imm5 = x0000 is reserved.
Operation

The description of DUP (element) gives the operational pseudocode for this instruction.
C7.2.185   MOV (element)

Move vector element to another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the INS (element) instruction. This means that:

• The encodings in this description are named to match the encodings of INS (element).
• The description of INS (element) gives the operational pseudocode for this instruction.

### Advanced SIMD variant

MOV <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

is equivalent to

INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

and is always the preferred disassembly.

### Assembler symbols

- **<Vd>**  
  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- **<Ts>**  
  Is an element size specifier, encoded in the "imm5" field. It can have the following values:

  - **B**  
    when imm5 = xxxx1
  - **H**  
    when imm5 = xxx10
  - **S**  
    when imm5 = xx100
  - **D**  
    when imm5 = x1000

  The encoding imm5 = x0000 is reserved.

- **<index1>**  
  Is the destination element index encoded in the "imm5" field. It can have the following values:

  - imm5<4:1>  
    when imm5 = xxxx1
  - imm5<4:2>  
    when imm5 = xxx10
  - imm5<4:3>  
    when imm5 = xx100
  - imm5<4>  
    when imm5 = x1000

  The encoding imm5 = x0000 is reserved.

- **<Vn>**  
  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- **<index2>**  
  Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

  - imm4<3:0>  
    when imm5 = xxxx1
  - imm4<3:1>  
    when imm5 = xxx10
  - imm4<3:2>  
    when imm5 = xx100
imm4<3> when imm5 = x1000
The encoding imm5 = x0000 is reserved.
Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

Operation

The description of INS (element) gives the operational pseudocode for this instruction.
C7.2.186 MOV (from general)

Move general-purpose register to a vector element. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the INS (general) instruction. This means that:

- The encodings in this description are named to match the encodings of INS (general).
- The description of INS (general) gives the operational pseudocode for this instruction.

```
| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 | 5 4 | 0 |
| 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | imm5 | 0 | 0 | 0 | 1 | 1 | Rn | Rd |
```

**Advanced SIMD variant**

MOV <Vd>.<Ts>[<index>], <R><n>

is equivalent to

INS <Vd>.<Ts>[<index>], <R><n>

and is always the preferred disassembly.

**Assembler symbols**

- `<Vd>`: Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ts>`: Is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - B when imm5 = xxxx1
  - H when imm5 = xxx10
  - S when imm5 = xx100
  - D when imm5 = x1000
  - The encoding imm5 = x0000 is reserved.
- `<index>`: Is the element index encoded in the "imm5" field. It can have the following values:
  - imm5<4:1> when imm5 = xxxx1
  - imm5<4:2> when imm5 = xxx10
  - imm5<4:3> when imm5 = xx100
  - imm5<4> when imm5 = x1000
  - The encoding imm5 = x0000 is reserved.
- `<R>`: Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:
  - W when imm5 = xxxx1
  - W when imm5 = xxx10
  - W when imm5 = xx100
  - X when imm5 = x1000
The encoding \texttt{imm5 = x0000} is reserved.

<\texttt{n}> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

**Operation**

The description of \texttt{INS (general)} gives the operational pseudocode for this instruction.
C7.2.187 MOV (vector)

Move vector. This instruction copies the vector in the source SIMD&FP register into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the ORR (vector, register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (vector, register).
- The description of ORR (vector, register) gives the operational pseudocode for this instruction.

Three registers of the same type variant

MOV <Vd>.<T>, <Vn>.<T>

is equivalent to

ORR <Vd>.<T>, <Vn>.<T>, <Vn>.<T>

and is the preferred disassembly when Rm == Rn.

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 8B when Q = 0
  - 16B when Q = 1
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of ORR (vector, register) gives the operational pseudocode for this instruction.
C7.2.188   MOV (to general)

Move vector element to general-purpose register. This instruction reads the unsigned integer from the source
SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination
general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the UMOV instruction. This means that:

- The encodings in this description are named to match the encodings of UMOV.
- The description of UMOV gives the operational pseudocode for this instruction.

```
[31 30 29 28][27 26 25 24][23 22 21 20] 16|15 14 13 12|11 10 9  |  5 4 |  0 |
  0 0 1 1 1 0 0 0 0 0 x x x 0 0 0 1 1 1 | Rn | Rd

32-bit variant

Applies when Q == 0 && imm5 == xx100.

MOV <Wd>, <Vn>.S[<index>]

is equivalent to

UMOV <Wd>, <Vn>.S[<index>]

and is always the preferred disassembly.

64-reg,UMOV-64-reg variant

Applies when Q == 1 && imm5 == x1000.

MOV <Xd>, <Vn>.D[<index>]

is equivalent to

UMOV <Xd>, <Vn>.D[<index>]

and is always the preferred disassembly.

Assembler symbols

<Wd>      Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd>      Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Vn>      Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<index>   For the 32-bit variant: is the element index encoded in "imm5<4:3>".
           For the 64-reg,UMOV-64-reg variant: is the element index encoded in "imm5<4>".

Operation

The description of UMOV gives the operational pseudocode for this instruction.
Move Immediate (vector). This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**8-bit variant**
Applies when \( op == 0 \land cmode == 1110 \).

\[
\text{MOVI} \ <Vd>.<T>, \ #\langle\text{imm8}\rangle\{, \ LSL \ #0}\]

**16-bit shifted immediate variant**
Applies when \( op == 0 \land cmode == 10x0 \).

\[
\text{MOVI} \ <Vd>.<T>, \ #\langle\text{imm8}\rangle\{, \ LSL \ #\langle\text{amount}\rangle}\]

**32-bit shifted immediate variant**
Applies when \( op == 0 \land cmode == 0xx0 \).

\[
\text{MOVI} \ <Vd>.<T>, \ #\langle\text{imm8}\rangle\{, \ LSL \ #\langle\text{amount}\rangle}\]

**32-bit shifting ones variant**
Applies when \( op == 0 \land cmode == 110x \).

\[
\text{MOVI} \ <Vd>.<T>, \ #\langle\text{imm8}\rangle, \ MSL \ #\langle\text{amount}\rangle\]

**64-bit scalar variant**
Applies when \( Q == 0 \land op == 1 \land cmode == 1110 \).

\[
\text{MOVI} \ <Dd>, \ #\langle\text{imm}\rangle\]

**64-bit vector variant**
Applies when \( Q == 1 \land op == 1 \land cmode == 1110 \).

\[
\text{MOVI} \ <Vd>.2D, \ #\langle\text{imm}\rangle\]

    result = operand AND NOT(imm);

V[rd] = result;
C7.2.190  MUL (by element)

Multiply (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<Ts>[<index>]

Decode for this encoding

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler symbols

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

4H    when size = 01, Q = 0
8H    when size = 01, Q = 1
2S    when size = 10, Q = 0
4S    when size = 10, Q = 1

The following encodings are reserved:
•    size = 00, Q = x.
•    size = 11, Q = x.

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>  Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

0:Rm    when size = 01
M:Rm    when size = 10
The following encodings are reserved:
- size = 00.
- size = 11.
Restricted to V0-V15 when element size $<$Ts$>$ is H.

$<$Ts$>$ is an element size specifier, encoded in the "size" field. It can have the following values:
- H when size = 01
- S when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

$<$index$>$ is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- $<$H:L:M$>$ when size = 01
- $<$H:L$>$ when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxsizeresult);
integer element1;
integer element2;
bits(esize) product;

element2 = UInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = UInt(Elem[operand1, e, esize]);
    product = (element1*element2)<esize-1:0>;
    Elem[result, e, esize] = product;

V[d] = result;
```
C7.2.191 MUL (vector)

Multiply (vector). This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

else
  product = (UInt(element1)*UInt(element2))<esize-1:0>;
Elem[result, e, esize] = product;

V[d] = result;
C7.2.192   MVN

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the NOT instruction. This means that:

- The encodings in this description are named to match the encodings of NOT.
- The description of NOT gives the operational pseudocode for this instruction.

Vector variant

MVN <Vd>.<T>, <Vn>.<T>
is equivalent to

NOT  <Vd>.<T>, <Vn>.<T>

and is always the preferred disassembly.

Assembler symbols

<Vd>   Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>    Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
        8B    when Q = 0
        16B   when Q = 1
<Vn>   Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of NOT gives the operational pseudocode for this instruction.
C7.2.193   MVNI

Move inverted Immediate (vector). This instruction places the inverse of an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

16-bit shifted immediate variant
Applies when cmode == 10x0.
MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}

32-bit shifted immediate variant
Applies when cmode == 0xx0.
MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}

32-bit shifting ones variant
Applies when cmode == 110x.
MVNI <Vd>.<T>, #<imm8>, MSL #<amount>

Decode for all variants of this encoding
integer rd = UInt(Rd);
integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
  when '0xx01' operation = ImmediateOp_MVNI;
  when '0xx11' operation = ImmediateOp_BIC;
  when '10x01' operation = ImmediateOp_MVNI;

  when '110x1' operation = ImmediateOp_MVNI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11111' // FMOV Dn,#imm is in main FP instruction set
    if Q == '0' then UnallocatedEncoding();
    operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
4H when Q = 0
8H when Q = 1

For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

2S when Q = 0
4S when Q = 1

<imm8>
Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount>
For the 16-bit shifted immediate variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

0 when cmode<1> = 0
8 when cmode<1> = 1
defaulting to 0 if LSL is omitted.

For the 32-bit shifted immediate variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

0 when cmode<2:1> = 00
8 when cmode<2:1> = 01
16 when cmode<2:1> = 10
24 when cmode<2:1> = 11
defaulting to 0 if LSL is omitted.

For the 32-bit shifting ones variant: is the shift amount encoded in the "cmode<0>" field. It can have the following values:

8 when cmode<0> = 0
16 when cmode<0> = 1

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI

integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

**Assembler symbols**

<\V>  Is a width specifier, encoded in the "size" field. It can have the following values:

- D  when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.
<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bias(datasize) operand = V[n];
bias(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```
C7.2.195   NOT

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MVN. The alias is always the preferred disassembly.

### Vector variant

NOT <Vd>.<T>, <Vn>.<T>

### Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

### Assembler symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 8B when Q = 0
  - 16B when Q = 1
- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = NOT(element);
V[d] = result;
```
C7.2.196 ORN (vector)

Bitwise inclusive OR NOT (vector). This instruction performs a bitwise OR NOT between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

ORN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

  8B when Q = 0
  16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
operand2 = NOT(operand2);
result = operand1 OR operand2;
V[d] = result;
C7.2.197   ORR (vector, immediate)

Bitwise inclusive OR (vector, immediate). This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise OR between each result and an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

16-bit variant

Applies when cmode == 10x1.

ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

32-bit variant

Applies when cmode == 0xx1.

ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

**Decode for all variants of this encoding**

integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;

bits(datasize) imm;

bits(64) imm64;

ImmediateOp operation;

case cmode:op of
  when '0xx00' operation = ImmediateOp_MOVI;
  when '0xx10' operation = ImmediateOp_ORR;
  when '10x00' operation = ImmediateOp_MOVI;
  when '10x10' operation = ImmediateOp_ORR;
  when '110x0' operation = ImmediateOp_MOVI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11110' operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);

imm = Replicate(imm64, datasize DIV 64);

**Assembler symbols**

<Vd> Is the name of the SIMD&FP register, encoded in the "Rd" field.

<T> For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0
8H when Q = 1

For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

2S when Q = 0
4S when Q = 1

<imm8> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h". 
<amount>  For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:
  0 when cmode<1> = 0
  8 when cmode<1> = 1
  defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:
  0 when cmode<2:1> = 00
  8 when cmode<2:1> = 01
  16 when cmode<2:1> = 10
  24 when cmode<2:1> = 11
  defaulting to 0 if LSL is omitted.

Operation

CheckFPAdvSIMDEnabled64();
b bits(datasize) operand;
b bits(datasize) result;

case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI
    result = NOT(imm);

    operand = V[rd];
    result = operand OR imm;
  when ImmediateOp_BIC
    operand = V[rd];
    result = operand AND NOT(imm);

V[rd] = result;
C7.2.198   ORR (vector, register)

Bitwise inclusive OR (vector, register). This instruction performs a bitwise OR between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (vector). See Alias conditions for details of when each alias is preferred.

Three registers of the same type variant
ORR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

if poly then
    product = PolynomialMult(element1, element2)<esize-1:0>;
else
    product = (UInt(element1)*UInt(element2))<esize-1:0>;
Elem[result, e, esize] = product;

V[d] = result;
C7.2.200  PMULL, PMULL2

Polynomial Multiply Long. This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see *Polynomial arithmetic over \{0, 1\} on page A1-49.*

The PMULL instruction extracts each source vector from the lower half of each source register, while the PMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

**Assembler symbols**

| 2 | Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
| [absent] | when Q = 0  
| [present] | when Q = 1  

</Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

</Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H  when size = 00
1Q  when size = 11

The following encodings are reserved:

- size = 01.
- size = 10.

The '1Q' arrangement is only allocated in an implementation that includes the Cryptographic Extension, and is otherwise RESERVED.

</Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **8B** when size = 00, Q = 0
- **16B** when size = 00, Q = 1
- **1D** when size = 11, Q = 0
- **2D** when size = 11, Q = 1

The following encodings are reserved:

- size = 01, Q = x.
- size = 10, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, 2*esize] = PolynomialMult(element1, element2);

V[d] = result;
```
C7.2.201 RADDHN, RADDHN2

Rounding Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see ADDHN, ADDHN2.

The RADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

```

**Assembler symbols**

<\Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<\vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element = 0;
integer rev_element;
for c = 0 to containers-1
    rev_element = element + elements_per_container - 1;
    for e = 0 to elements_per_container-1
        Elem[result, rev_element, esize] = Elem[operand, element, esize];
        element = element + 1;
        rev_element = rev_element - 1;

V[d] = result;
```

C7.2.207 RSHRN, RSHRN2

Rounding Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SHRN, SHRN2.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

RSHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');

Assembler symbols

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

Absent when Q = 0
Present when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
The encoding $\text{immh} = 1xxx$, $Q = x$ is reserved.

$\texttt{<Vn>}$ is the name of the SIMD&FP source register, encoded in the "Rn" field.

$\texttt{<Ta>}$ is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- $8H$ when $\text{immh} = 0001$
- $4S$ when $\text{immh} = 001x$
- $2D$ when $\text{immh} = 01xx$

See *Advanced SIMD modified immediate on page C4-306* when $\text{immh} = 0000$.

The encoding $\text{immh} = 1xxx$ is reserved.

$\texttt{<shift>}$ is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immb:immb" field. It can have the following values:

- $(16-\text{UInt}(\text{immh}:\text{immb}))$ when $\text{immh} = 0001$
- $(32-\text{UInt}(\text{immh}:\text{immb}))$ when $\text{immh} = 001x$
- $(64-\text{UInt}(\text{immh}:\text{immb}))$ when $\text{immh} = 01xx$

See *Advanced SIMD modified immediate on page C4-306* when $\text{immh} = 0000$.

The encoding $\text{immh} = 1xxx$ is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bons(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
for e = 0 to elements-1
  element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
  Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```

C7.2.208   RSUBHN, RSUBHN2

Rounding Subtract returning High Narrow. This instruction subtracts each vector element of the second source
SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most
significant half of the result into a vector, and writes the vector to the lower or upper half of the destination
SIMD&FP register.

The results are rounded. For truncated results, see SUBHN, SUBHN2.

The RSUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while
the RSUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits
of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Q</td>
<td>1</td>
</tr>
</tbody>
</table>
```

Three registers, not all the same type variant

RSUBHN(2) <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

Decode for this encoding

```java
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

Assembler symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper
64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

| absent | when Q = 0 |
| present | when Q = 1 |

<Vd>

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>

Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |
The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;
for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;
Vpart[d, part] = result;
```
C7.2.209  SABA

Signed Absolute difference and Accumulate. This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the elements of the vector of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

SABA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2     Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
   [absent] when Q = 0
   [present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:
   8H    when size = 00
   4S    when size = 01
   2D    when size = 10

The encoding size = 11 is reserved.

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
   8B    when size = 00, Q = 0
   16B   when size = 00, Q = 1
The encoding size = 11, Q = x is reserved.

\( <Vm> \) is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

SADDLP

Signed Add Long Pairwise. This instruction adds pairs of adjacent signed integer values from the vector in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SADDLP <Vd>.<Ta>, <Vn>.<Tb>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV (2 * esize);
boolean acc = (op == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ta>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - `4H` when size = 00, Q = 0
  - `8H` when size = 00, Q = 1
  - `2S` when size = 01, Q = 0
  - `4S` when size = 01, Q = 1
  - `1D` when size = 10, Q = 0
  - `2D` when size = 10, Q = 1
  The encoding size = 11, Q = x is reserved.
- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- `<Tb>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - `8B` when size = 00, Q = 0
  - `16B` when size = 00, Q = 1
  - `4H` when size = 01, Q = 0
  - `8H` when size = 01, Q = 1
  - `2S` when size = 10, Q = 0
  - `4S` when size = 10, Q = 1
  The encoding size = 11, Q = x is reserved.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(2*esize) sum;
integer op1;
integer op2;

result = if acc then V[d] else Zeros();
for e = 0 to elements-1
    op1 = Int(Elem[operand, 2*e+0, esize], unsigned);
    op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
    sum = (op1+op2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;
V[d] = result;
C7.2.216  SADDLV

Signed Add Long across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 |  5 4 |  0 |
| 0 Q 0 0 1 1 0 |size 1 1 0 0|0 0 0 1 1 0 |Rn | Rd |
```

**Advanced SIMD variant**

SADDLV <V><d>, <Vn>.<T>

**Decode for this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
if size == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

**Assembler symbols**

- `<V>`: Is the destination width specifier, encoded in the "size" field. It can have the following values:
  - H  when size = 00
  - S  when size = 01
  - D  when size = 10
  
  The encoding size = 11 is reserved.

- `<d>`: Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- `<Vn>`: Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<T>`: Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B  when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H  when size = 01, Q = 0
  - 8H  when size = 01, Q = 1
  - 4S  when size = 10, Q = 1

  The following encodings are reserved:
  - `size = 10, Q = 0`.
  - `size = 11, Q = x`. 

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer sum;

sum = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    sum = sum + Int(Elem[operand, e, esize], unsigned);

V[d] = sum<2*esize-1:0>;
```
C7.2.217 SADDW, SADDW2

Signed Add Wide. This instruction adds vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the results in a vector, and writes the vector to the SIMD&FP destination register.

The SADDW instruction extracts the second source vector from the lower half of the second source register, while the SADDW2 instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

</tr>
</tbody>
</table>
```

Three registers, not all the same type variant

SADDW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
datatype = 64;
integer part = UInt(Q);
integer elements = datatype DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8H when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```
C7.2.218 SCVT (vector, fixed-point)

Signed fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

**Scalar**

```
| 31 30 29 28|27 26 25 24|23 22 | 19 18 16|15 14 13 12|11 10 9 | 5 4 | 0 |
| 0 1 0 1 1 1 1 0 | 1 1 1 0 0 1 | Rd | Rn |
```

**Scalar variant**

SCVT <V><d>, <V><n>, #<fbits>

*Decode for this encoding*

integer d = UInt(Rd);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh == '000x' || (immh == '001x' && !HaveFP16Ext()) then ReservedValue();
if immh<3>:Q == '10' then ReservedValue();
iinteger esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
iinteger datasize = if Q == '1' then 128 else 64;
iinteger elements = datasize DIV esize;
integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:
   H when immh = 001x
   S when immh = 01xx
   D when immh = 1xxx
   The encoding immh = 000x is reserved.
<\d> Is the number of the SIMD&FP destination register, in the "Rd" field.
<\n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<\Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
   4H when immh = 001x, Q = 0
   8H when immh = 001x, Q = 1
   2S when immh = 01xx, Q = 0
   4S when immh = 01xx, Q = 1
   2D when immh = 1xxx, Q = 1
   See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
   The following encodings are reserved:
   • immh = 0001, Q = x.
   • immh = 1xxx, Q = 0.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:
   (32-UInt(immh:immb)) when immh = 001x
   (64-UInt(immh:immb)) when immh = 01xx
   (128-UInt(immh:immb)) when immh = 1xxx
   The encoding immh = 000x is reserved.
   For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:
   (32-UInt(immh:immb)) when immh = 001x
   (64-UInt(immh:immb)) when immh = 01xx
   (128-UInt(immh:immb)) when immh = 1xxx
   See Advanced SIMD modified immediate on page C4-306 when immh = 0000.
   The encoding immh = 0001 is reserved.

Operation for all encodings

CheckFPAdvSIMDEnabled64();

bits(intsize) intval;

intval = X[n];
fltval = FixedToFP(intval, 0, FALSE, FPCR, rounding);
V[d] = fltval;
C7.2.222   SDOT (by element)

Dot Product signed arithmetic (vector, by element). This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

From ARMv8.2, this is an OPTIONAL instruction.

Note: ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

ARMv8.2

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 16|15 14 13 12|11 10 9 | 5 4 | 0 |
0 Q 0 1 1 1 1 size L M Rm 1 1 1 0 H 0 Rn Rd
```

Vector variant

SDOT <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.4B[<index>]

Decode for this encoding

```
if !HaveDOTPExt() then UNDEFINED;
if size != '10' then ReservedValue();
boolean signed = (U == '0');

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(M:Rm);
integer index = UInt(H:L);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
2S when Q = 0
4S when Q = 1
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Tb> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
8B when Q = 0
16B when Q = 1
<Vm> Is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.
<index> Is the element index, encoded in the "H:L" fields.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(128) operand2 = V[m];
bits(datasize) result = V[d];
for e = 0 to elements-1

```
C7.2.234 SHA512H

SHA512 Hash update part 1 takes the values from the three 128-bit source SIMD&FP registers and produces a 128-bit output value that combines the sigma1 and chi functions of two iterations of the SHA512 computation. It returns this value to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

Advanced SIMD variant

SHA512H <Qd>, <Qn>, <Vm>.2D

Decode for this encoding

if !HaveCryptoExt2() then UnallocatedEncoding();
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

Assembler symbols

<Qd> Is the 128-bit name of the SIMD&FP source and destination register, encoded in the "Rd" field.
<Qn> Is the 128-bit name of the second SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the third SIMD&FP source register, encoded in the "Rm" field.

Operation

bits(128) Vtmp;
bits(64) MSigma1;
bits(64) tmp;
bits(128) X = V[n];
bits(128) Y = V[m];
bits(128) W = V[d];

MSigma1 = ROR(Y<127:64>, 14) EOR ROR(Y<127:64>, 18) EOR ROR(Y<127:64>, 41);
Vtmp<127:64> = (Y<127:64> AND X<63:0>) EOR (NOT(Y<127:64>) AND X<127:64>);
Vtmp<127:64> = (Vtmp<127:64> + MSigma1 + W<127:64>);
tmp = Vtmp<127:64> + Y<63:0>;
MSigma1 = ROR(tmp, 14) EOR ROR(tmp, 18) EOR ROR(tmp, 41);
Vtmp<63:0> = (tmp AND Y<127:64>) EOR (NOT(tmp) AND X<63:0>);
Vtmp<63:0> = (Vtmp<63:0> + MSigma1 + W<63:0>);
V[d] = Vtmp;
C7.2.235 SHA512H2

SHA512 Hash update part 2 takes the values from the three 128-bit source SIMD&FP registers and produces a 128-bit output value that combines the sigma0 and majority functions of two iterations of the SHA512 computation. It returns this value to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

**Advanced SIMD variant**

SHA512H2 <Qd>, <Qn>, <Vm>.2D

Three registers of the same type variant

SHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size-Q" field. It can have the following values:
    8B when size = 00, Q = 0
    16B when size = 00, Q = 1
    4H when size = 01, Q = 0
    8H when size = 01, Q = 1
    2S when size = 10, Q = 0
    4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  sum = element1 + element2;
  Elem[result, e, esize] = sum<esize:1>;

V[d] = result;
C7.2.239   SHL

Shift Left (immediate). This instruction reads each value from a vector, left shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
0 1 0 1 1 1 1 0 | 0000 | 0 0 0 1 1 1 1 | Rn | Rd

immh
```

**Scalar variant**

SHL <V><d>, <V><n>, #<shift>

**Decode for this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;
integer shift = UInt(immh:immb) - esize;
```

Vector

```
0 0 0 1 1 1 1 0 | 0000 | 0 0 0 1 1 1 1 | Rn | Rd

immh
```

**Vector variant**

SHL <Vd><T>, <Vn><T>, #<shift>

**Decode for this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer shift = UInt(immh:immb) - esize;
```

**Assembler symbols**

<V>     Is a width specifier, encoded in the "immh" field. It can have the following values:

- D  when immh = 1xxx

The encoding immh = 0xxx is reserved.
<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

</d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1
- 2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = 0 is reserved.

</n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-64) when immh = 1xxx

The encoding immh = 0xxx is reserved.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx
- (UInt(immh:immb)-64) when immh = 1xxx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
for e = 0 to elements-1
  Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);
V[d] = result;
C7.2.240 SHLL, SHLL2

Shift Left Long (by element size). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SHLL instruction extracts vector elements from the lower half of the source register, while the SHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SHLL(2) <Vd>,<Ta>, <Vn>,<Tb>, #<shift>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = esize;
boolean unsigned = FALSE;    // Or TRUE without change of functionality

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
8H  when size = 00
4S  when size = 01
2D  when size = 10

The encoding size = 11 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B  when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<shift> Is the left shift amount, which must be equal to the source element width in bits, encoded in the "size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10

The encoding size = 11 is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias(datasize) operand = Vpart[n, part];
bias(2*datasize) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```
C7.2.241 SHRN, SHRN2

Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see RSHRN, RSHRN2.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SHRN[2] <Vd>,<Tv>, <Vn>,<Tn>, #<shift>

Decode for this encoding

```markdown
integer d = UInt(Rd);
integer n = UInt(Rn);
if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  - [absent] when Q = 0
  - [present] when Q = 1

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- <Tv> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
  - 8 when immh = 0001, Q = 0
  - 16 when immh = 0001, Q = 1
  - 4 when immh = 001x, Q = 0
  - 8 when immh = 00lx, Q = 1
  - 2 when immh = 01xx, Q = 0
  - 4 when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<n>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

The encoding immh = 1xxx is reserved.

<shift>
Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- (16-UInt(immh:immb)) when immh = 0001
- (32-UInt(immh:immb)) when immh = 001x
- (64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

The encoding immh = 1xxx is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bots(datasize*2) operand = V[n];
bots(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```
C7.2.242   SHSUB

Signed Halving Subtract. This instruction subtracts the elements in the vector in the second source SIMD&FP register from the corresponding elements in the vector in the first source SIMD&FP register, shifts each result right one bit, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

SHSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = Uint(Rd);
integer n = Uint(Rn);
integer m = Uint(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << Uint(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<Vd>   Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>   Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B   when size = 00, Q = 0
16B   when size = 00, Q = 1
4H   when size = 01, Q = 0
8H   when size = 01, Q = 1
2S   when size = 10, Q = 0
4S   when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn>   Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>   Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnable64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    result[e] = (element1 - element2) >> 1;

write to vector <Vd>
element2 = Int(Elem[operand2, e, esize], unsigned);
diff = element1 - element2;
Elem[result, e, esize] = diff<esize:1>;

V[d] = result;
C7.2.243  SLI

Shift Left and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, left
shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the
destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their
existing value. Bits shifted out of the left of each vector element in the source register are lost.

The following figure shows the operation of shift left by 3 for an 8-bit vector element.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

**Scalar**

```
| 31 30 29 28 | 27 26 25 24 | 23 22 | | 19 18 | 16 | 15 14 13 12 | 11 10 9 | | 5 4 | 0 |

```

**Vector variant**

SLI <Vd>.<T>, <Vn>.<T>, #<shift>
Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer shift = UInt(immh:immb) - esize;
```

Assembler symbols

<\V> Is a width specifier, encoded in the "immh" field. It can have the following values:

- D when immh = 1xxx
  The encoding immh = 0xxx is reserved.

<\d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<\n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

</d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1
- 2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = 0 is reserved.

<\Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<\shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-64) when immh = 1xxx
  The encoding immh = 0xxx is reserved.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx
- (UInt(immh:immb)-64) when immh = 1xxx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2 = V[d];
bits(datasize) result;
```
bits(esize) mask = LSL(Ones(esize), shift);
bits(esize) shifted;
for e = 0 to elements-1
    shifted = LSL(Elem[operand, e, esize], shift);
    Elem[result, e, esize] = (Elem[operand2, e, esize] AND NOT(mask)) OR shifted;
V[d] = result;
SM3PARTW1

SM3PARTW1 takes three 128-bit vectors from the three source SIMD&FP registers and returns a 128-bit result in the destination SIMD&FP register. The result is obtained by a three-way exclusive OR of the elements within the input vectors with some fixed rotations, see the Operation pseudocode for more information.

This instruction is implemented only when ARMv8.2-SM is implemented.

bits(128) Va = V[a];
Vd<127:96> = ROL((ROL(Vn<127:96>, 12) + Vm<127:96> + Va<127:96>), 7);
Vd<95:0> = Zeros();
V[d] = Vd;
C7.2.247  SM3TT1A

SM3TT1A takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive OR.
- The result of the exclusive OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

This instruction is implemented only when ARMv8.2-SM is implemented.

    roundresult<31:0> = roundresult<63:32>;
    roundresult<63:32> = roundresult<95:64>;
    roundresult<95:64> = roundresult<127:96>;
    roundresult<127:96> = intval;
V[d] = roundresult;
C7.2.252 SM4EKEY

SM4 Key takes an input as a 128-bit vector from the first source SIMD&FP register and a 128-bit constant from the second SIMD&FP register. It derives four iterations of the output key, in accordance with the SM4 standard, returning the 128-bit result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SM is implemented.

ARMv8.2

```
<table>

    roundresult<127:96> = intval;
V[d] = roundresult;
### C7.2.253 SMAX

Signed Maximum (vector). This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the larger of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Three registers of the same type variant

SMAX <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

#### Decode for this encoding

```plaintext
type d = UInt(Rd);
type n = UInt(Rn);
type m = UInt(Rm);
if size == '11' then ReservedValue();
type esize = 8 << UInt(size);
type datasize = if Q == '1' then 128 else 64;
type elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

#### Assembler symbols

- `<Vd>`: Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>`: Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - `8B` when `size = 00`, `Q = 0`
  - `16B` when `size = 00`, `Q = 1`
  - `4H` when `size = 01`, `Q = 0`
  - `8H` when `size = 01`, `Q = 1`
  - `2S` when `size = 10`, `Q = 0`
  - `4S` when `size = 10`, `Q = 1`

The encoding `size = 11`, `Q = x` is reserved.

- `<Vn>`: Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>`: Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

#### Operation

```plaintext
CheckFPAdvSIMDEnable64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer maxmin;
```
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
  Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
C7.2.254  SMAXP

Signed Maximum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

   element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);
   maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
   Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
SMAXV

Signed Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

SMAXV <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean min = (op == '1');

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
- B when size = 00
- H when size = 01
- S when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 4S when size = 10, Q = 1

The following encodings are reserved:
- size = 10, Q = 0.
- size = 11, Q = x.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin×size-1:0;
```
C7.2.256  SMIN

Signed Minimum (vector). This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the smaller of each of the two signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 18 17 16 | 15 14 13 12 | 11 10 9 8 7 6 5 4 3 2 1 0 |

  maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin-size-1:0;
### C7.2.259   **SMLAL, SMLAL2 (by element)**

Signed Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

The SMLAL instruction extracts vector elements from the lower half of the first source register, while the SMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Vector variant

**SMLAL[2] <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]**

#### Decode for this encoding

```plaintext
integer idxdsze = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UnallocatedEncoding();
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
```

#### Assembler symbols

- **2** is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  - [absent] when Q = 0
  - [present] when Q = 1

- **<Vd>** is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- **<Ta>** is an arrangement specifier, encoded in the "size" field. It can have the following values:
  - 4S when size = 01
  - 2D when size = 10
The following encodings are reserved:

- \( \text{size} = 00 \)
- \( \text{size} = 11 \)

\(<\text{n}>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<\text{tb}>\) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- \(4H\) when \( \text{size} = 01, Q = 0\)
- \(8H\) when \( \text{size} = 01, Q = 1\)
- \(2S\) when \( \text{size} = 10, Q = 0\)
- \(4S\) when \( \text{size} = 10, Q = 1\)

The following encodings are reserved:

- \( \text{size} = 00, Q = x \)
- \( \text{size} = 11, Q = x \)

\(<\text{vm}>\) Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

- \(0:Rm\) when \( \text{size} = 01\)
- \(M:Rm\) when \( \text{size} = 10\)

The following encodings are reserved:

- \( \text{size} = 00 \)
- \( \text{size} = 11 \)

Restricted to V0-V15 when element size \( <Ts>\) is H.

\(<\text{ts}>\) Is an element size specifier, encoded in the "size" field. It can have the following values:

- \(H\) when \( \text{size} = 01\)
- \(S\) when \( \text{size} = 10\)

The following encodings are reserved:

- \( \text{size} = 00 \)
- \( \text{size} = 11 \)

\(<\text{index}>\) Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- \(H:L:M\) when \( \text{size} = 01\)
- \(H:L\) when \( \text{size} = 10\)

The following encodings are reserved:

- \( \text{size} = 00 \)
- \( \text{size} = 11 \)

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias<datasize> operand1 = Vpart[n, part];
bias(idxdsize) operand2 = V[m];
bias(2*datasize) operand3 = V[d];
bias(2*datasize) result;
integer element1;
integer element2;
bias<2*esize> product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<<2*esize-1:0;
```

if sub_op then
    Elem[result, e, 2*size] = Elem[operand3, e, 2*size] - product;
else
    Elem[result, e, 2*size] = Elem[operand3, e, 2*size] + product;

V[d] = result;
### SMLAL, SMLAL2 (vector)

Signed Multiply-Add Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLAL instruction extracts each source vector from the lower half of each source register, while the SMLAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
The encoding size = 11, Q = x is reserved.

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

\[\text{CheckFPAdvSIMDEnabled64}();\]
\[\text{bits(datasize) operand1 = Vpart}[n, \text{ part}];\]
\[\text{bits(datasize) operand2 = Vpart}[m, \text{ part}];\]
\[\text{bits(2*datasize) operand3 = V}[d];\]
\[\text{bits(2*datasize) result};\]
\[\text{integer element1};\]
\[\text{integer element2};\]
\[\text{bits(2*esize) product};\]
\[\text{bits(2*esize) accum};\]

\[\text{for e = 0 to elements-1}\]
\[\text{element1} = \text{Int(Elem}[\text{operand1}, e, \text{ esize}], \text{ unsigned});\]
\[\text{element2} = \text{Int(Elem}[\text{operand2}, e, \text{ esize}], \text{ unsigned});\]
\[\text{product} = (\text{element1} \times \text{element2})<2*\text{esize}-1:0>;\]
\[\text{if sub_op then}\]
\[\text{accum} = \text{Elem}[\text{operand3}, e, 2*\text{esize}] - \text{product};\]
\[\text{else}\]
\[\text{accum} = \text{Elem}[\text{operand3}, e, 2*\text{esize}] + \text{product};\]
\[\text{Elem}[\text{result}, e, 2*\text{esize}] = \text{accum};\]
\[\text{V}[d] = \text{result};\]
C7.2.261  SMLSL, SMLSL2 (by element)

Signed Multiply-Subtract Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts vector elements from the lower half of the first source register, while the SMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SMLSL{2} <Vd>,<Ta>, <Vn>,<Tb>, <Vm>,<Ts>[<index>]

Decode for this encoding

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UnallocatedEncoding();
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  [absent] when Q = 0
  [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  4S when size = 01
  2D when size = 10

The following encodings are reserved:
  • size = 00.
• size = 11.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

- 0:Rm when size = 01
- M:Rm when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- H:L:M when size = 01
- H:L when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

### Operation

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<<(2*esize-1:0);
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else
```

```c
```
\[ \text{Elem}[\text{result, e, 2\text{esize}}] = \text{Elem}[\text{operand3, e, 2\text{esize}}] + \text{product}; \]

\[ V[d] = \text{result}; \]
SMLSL, SMLSL2 (vector)

Signed Multiply-Subtract Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts each source vector from the lower half of each source register, while the SMLSL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Decoding for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

### Assembler symbols

- `2`: The second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  - [absent] when Q = 0
  - [present] when Q = 1

- `<Vd>`: Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- `<Ta>`: Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  - 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10

The encoding size = 11 is reserved.

- `<Vn>`: Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

- `<Tb>`: Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<\Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1*element2)<<2*esize-1:0>
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```
C7.2.263  SMOV

Signed Move vector element to general-purpose register. This instruction reads the signed integer from the source SIMD&FP register, sign-extends it to form a 32-bit or 64-bit value, and writes the result to destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

32-bit variant

Applies when Q == 0.

\[ \text{SMOV} \ <\text{Wd}>, \ <\text{Vn}>.\text{<Ts>}[<index>] \]

64-reg, SMOV-64-reg variant

Applies when Q == 1.

\[ \text{SMOV} \ <\text{Xd}>, \ <\text{Vn}>.\text{<Ts>}[<index>] \]

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size;

case Q:imm5 of
  when 'xxxxx1' size = 0;    // SMOV \[WX\]d, Vn.B
  when 'xxxx10' size = 1;    // SMOV \[WX\]d, Vn.H
  when '1xx100' size = 2;    // SMOV Xd, Vn.S
  otherwise UnallocatedEncoding();

integer idxdsize = if imm5<4> == '1' then 128 else 64;
integer index = UInt(imm5<4:size+1>);
integer esize = 8 << size;
integer datasize = if Q == '1' then 64 else 32;

Assembler symbols

\(<\text{Wd}>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
\(<\text{Xd}>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
\(<\text{Vn}>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.
\(<\text{Ts}>\) For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:
  B  when imm5 = xxxx1
  H  when imm5 = xxxx10
The encoding imm5 = xxxx0 is reserved.

For the 64-reg, SMOV-64-reg variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:
  B  when imm5 = xxxx1

[31 30 29 28]27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 | 0 | 5 4 | 0 |
| 0 | Q | 0 | 1 | 1 | 0 | 0 | 0 | imm5 | 0 | 0 | 1 | 0 | 1 | 1 | Rn | Rd |
H when \( \text{imm5} = \text{xxx10} \)
S when \( \text{imm5} = \text{xx100} \)

The encoding \( \text{imm5} = \text{xx000} \) is reserved.

<index>

For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:
- \( \text{imm5}\langle 4:1 \rangle \) when \( \text{imm5} = \text{xxxx1} \)
- \( \text{imm5}\langle 4:2 \rangle \) when \( \text{imm5} = \text{xxx10} \)
The encoding \( \text{imm5} = \text{xxx00} \) is reserved.

For the 64-reg,SMOV-64-reg variant: is the element index encoded in the "imm5" field. It can have the following values:
- \( \text{imm5}\langle 4:1 \rangle \) when \( \text{imm5} = \text{xxxx1} \)
- \( \text{imm5}\langle 4:2 \rangle \) when \( \text{imm5} = \text{xxx10} \)
- \( \text{imm5}\langle 4:3 \rangle \) when \( \text{imm5} = \text{xx100} \)
The encoding \( \text{imm5} = \text{xx000} \) is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(idxsize) operand = V[n];

X[d] = SignExtend(Elem[operand, index, esize], datasize);
```
C7.2.264  SMULL, SMULL2 (by element)

Signed Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMULL instruction extracts vector elements from the lower half of the first source register, while the SMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant
SMULL[2] <Vd>,<Ta>, <Vn>,<Tb>, <Vm>,<Ts>[<index>]

Decode for this encoding

```
integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

  [absent]  when Q = 0
  [present]  when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

  4S  when size = 01
  2D  when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.
<Vn> is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

<Vm> is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

- 0:Rm when size = 01
- M:Rm when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> is an element size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<index> is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- H:L:M when size = 01
- H:L when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  product = (element1*element2)<2*esize-1:0>;
  Elem[result, e, 2*esize] = product;
V[d] = result;
C7.2.265  SMULL, SMULL2 (vector)

Signed Multiply Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

The destination vector elements are twice as long as the elements that are multiplied.

The SMULL instruction extracts each source vector from the lower half of each source register, while the SMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

SMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');

Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  [absent]  when Q = 0
  [present]  when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Va>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  8H  when size = 00
  4S  when size = 01
  2D  when size = 10
The encoding size = 11 is reserved.

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  8B  when size = 00, Q = 0
  16B  when size = 00, Q = 1
4H  when size = 01, Q = 0
8H  when size = 01, Q = 1
2S  when size = 10, Q = 0
4S  when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vm>  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;

for e = 0 to elements-1
   element1 = Int(Elem[operand1, e, esize], unsigned);
   element2 = Int(Elem[operand2, e, esize], unsigned);
   Elem[result, e, 2*esize] = (element1*element2)<2*esize-1:0>;

V[d] = result;
C7.2.266   SQABS

Signed saturating Absolute value. This instruction reads each vector element from the source SIMD&FP register, puts the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

SQABS <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

B when size = 00
H when size = 01
S when size = 10
D     when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size-Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    (Elem[result, e, esize], sat) = SignedSatQ(element, esize);
    if sat then FPSR.QC = '1';

V[d] = result;
```
**C7.2.267   SQADD**

Signed saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Assembler symbols**

`<V>`

Is a width specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
D  when size = 11

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
boolean sat;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    (Elem[result, e, esize], sat) = SatQ(sum, esize, unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
C7.2.268 SQDMLAL, SQDMLAL2 (by element)

Signed saturating Doubling Multiply-Add Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMLAL instruction extracts vector elements from the lower half of the first source register, while the SQDMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.272 SQDMULH (by element)

Signed saturating Doubling Multiply returning High half (by element). This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SQRDMULH (by element).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';
V[d] = result;
```
C7.2.274  SQDMULL, SQDMULL2 (by element)

Signed saturating Doubling Multiply Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMULL instruction extracts the first source vector from the lower half of the first source register, while the SQDMULL2 instruction extracts the first source vector from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

4S when size = 01
2D when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The following encodings are reserved:
• size = 00, Q = x.
• size = 11, Q = x.

<Va> Is the destination width specifier, encoded in the "size" field. It can have the following values:

S when size = 01
D when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vb> Is the source width specifier, encoded in the "size" field. It can have the following values:

H when size = 01
S when size = 10
The following encodings are reserved:
- size = 00.
- size = 11.

<n> is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

0:Rm when size = 01
M:Rm when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> is an element size specifier, encoded in the "size" field. It can have the following values:

H when size = 01
S when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

<index> is the element index, encoded in the "size:L:H:M" field. It can have the following values:

H:L:M when size = 01
H:L when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

Operation for all encodings

```
Assembler symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
- [present] when Q = 1

<vd>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>
Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 4S when size = 01
- 2D when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

<Vn>
Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb>
Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:
- size = 00, Q = x.
- size = 11, Q = x.

<Vm>
Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Va>
Is the destination width specifier, encoded in the "size" field. It can have the following values:
- S when size = 01
- D when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

<d>
Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<vb>
Is the source width specifier, encoded in the "size" field. It can have the following values:
- H when size = 01
- S when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

<tn>
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<tt>
Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;

- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<\</n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
  element = SInt(Elem[operand, e, esize]);
  if neg then
    element = -element;
  else
    element = Abs(element);
  (Elem[result, e, esize], sat) = SignedSatQ(element, esize);
  if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.277 SQRDMLAH (by element)

Signed Saturating Rounding Doubling Multiply Accumulate returning High Half (by element). This instruction multiplies the vector elements of the first source SIMD&FP register with the value of a vector element of the second source SIMD&FP register without saturating the multiply results, doubles the results, and accumulates the most significant half of the final results with the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSR.QC, is set if saturation occurs.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

* size = 00.
* size = 11.

Restricted to V0-V15 when element size <\Ts> is H.

<\Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:

H when size = 01
S when size = 10

The following encodings are reserved:

* size = 00.
* size = 11.
Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- H:L:M when size = 01
- H:L when size = 10

The following encodings are reserved:

- size = 00
- size = 11

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxsize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
integer element1;
integer element2;
integer product;
boolean sat;

element2 = SInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = SInt(Elem[operand1, e, esize]);
    product = (2 * element1 * element2) + round_const;
    // The following only saturates if element1 and element2 equal -(2^(esize-1))
    (Elem[result, e, esize], sat) = SignedSatQ(product >> esize, esize);
    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.282 SQRDMULH (vector)

Signed saturating Rounding Doubling Multiply returning High half. This instruction multiplies the values of corresponding elements of the two source SIMD&FP registers, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQDMULH (vector).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Scalar**

integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = datasize DIV esize;
boolean rounding = (U == '1');
```

**Assembler symbols**

\( <V> \)

Is a width specifier, encoded in the "size" field. It can have the following values:

- \( H \) when size = 01
S when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<d>
Is the number of the SIMD&FP destination register, in the "Rd" field.

<n>
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m>
Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

</d>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>
Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

</n>
Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

</m>
Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if rounding then 1 << (esize - 1) else 0;
integer element1;
integer element2;
integer product;
boolean sat;
for e = 0 to elements-1
    element1 = SInt(Elem[operand1, e, esize]);
    element2 = SInt(Elem[operand2, e, esize]);
    product = (2 * element1 * element2) + round_const;
    (Elem[result, e, esize], sat) = SignedSatQ(product >> esize, esize);
    if sat then FPSR.QC = '1';
V[d] = result;
```

C7.2.283   SQRSHL

Signed saturating Rounding Shift Left (register). This instruction takes each vector element in the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see SQSHL (register).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

            Elem[result, e, esize] = element<esize-1:0>;
    sat = sat | (round_const != 0);

V[d] = result;
C7.2.284  SQRSHRN, SQRSHRN2

Signed saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SQRSHRN, SQRSHRN2.

The SQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1
</d>
<</Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<</Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<</Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<</Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx
See Advanced SIMD modified immediate on page C4-306 when immh = 0000.
The encoding immh = 1xxx is reserved.

<</Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:
B when immh = 0001
H when immh = 001x
S when immh = 01xx
The following encodings are reserved:
• immh = 0000.
• immh = 1xxx.
<</d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<</Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:
H when immh = 0001
S when immh = 001x
D when immh = 01xx
The following encodings are reserved:
- immh = 0000.
- immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:
- (16-UInt(immh:immb)) when immh = 0001
- (32-UInt(immh:immb)) when immh = 001x
- (64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:
- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:
- (16-UInt(immh:immb)) when immh = 0001
- (32-UInt(immh:immb)) when immh = 001x
- (64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation for all encodings

CheckFPAdVIMDEnabled64();
bias(datasize*2) operand = V[n];
bias(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
  element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
  (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
  if sat then FPSR.QC = '1';
Vpart[d, part] = result;
C7.2.285 SQRSHRUN, SQRSHRUN2

Signed saturating Rounded Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are rounded. For truncated results, see SQRSHRUN, SQRSHRUN2.

The SQRSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

See Advanced SIMD modified immediate on page C4-306 when \(\text{immh} = 0000\).

The encoding \(\text{immh} = 1xxx\) is reserved.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
    element = (SInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    (Elem[result, e, esize], sat) = UnsignedSatQ(element, esize);
    if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```

C7.2.286   SQSHL (immediate)

Signed saturating Shift Left (immediate). This instruction reads each vector element in the source SIMD&FP
register, shifts each result by an immediate value, places the final result in a vector, and writes the vector to the
destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation
bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Assembler symbols

\textless V \textgreater 
Is a width specifier, encoded in the "immh" field. It can have the following values:
B when immh = 0001
H when immh = 001x
S when immh = 01xx
D when immh = 1xxx
The encoding immh = 0000 is reserved.

\textless d \textgreater 
Is the number of the SIMD&FP destination register, in the "Rd" field.

\textless n \textgreater 
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\textless Vd \textgreater 
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\textless T \textgreater 
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
2D when immh = 1xxx, Q = 1
See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = 0 is reserved.

\textless Vn \textgreater 
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\textless \text{shift} \textgreater 
For the scalar variant: is the left shift amount, in the range 0 to the operand width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
(UInt(immh:immb)-8) when immh = 0001
(UInt(immh:immb)-16) when immh = 001x
(UInt(immh:immb)-32) when immh = 01xx
(UInt(immh:immb)-64) when immh = 1xxx
The encoding immh = 0000 is reserved.
For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
(UInt(immh:immb)-8) when immh = 0001
(UInt(immh:immb)-16) when immh = 001x
(UInt(immh:immb)-32) when immh = 01xx
(UInt(immh:immb)-64) when immh = 1xxx
See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

**Operation for all encodings**

    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
C7.2.287   SQSHL (register)

Signed saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see SQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.289   SQSHRN, SQSHRN2

Signed saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see SQRSHRN, SQRSHRN2.

The SQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Assembler symbols**

2  
Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd>  
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn>  
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb>  
Is the destination width specifier, encoded in the "immh" field. It can have the following values:

- B when immh = 0001
- H when immh = 001x
- S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d>  
Is the number of the SIMD&FP destination register, in the "Rd" field.

<va>  
Is the source width specifier, encoded in the "immh" field. It can have the following values:

- H when immh = 0001
- S when immh = 001x
- D when immh = 01xx
The following encodings are reserved:

- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

\(<n>\) Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\(<\text{shift}>\) For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

- \( (16-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 0001 \)
- \( (32-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 001x \)
- \( (64-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 01xx \)

The following encodings are reserved:

- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- \( (16-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 0001 \)
- \( (32-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 001x \)
- \( (64-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 01xx \)

See Advanced SIMD modified immediate on page C4-306 when \( \text{immh} = 0000 \).

The encoding \( \text{immh} = 1xxx \) is reserved.

**Operation for all encodings**

```assembly
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```
C7.2.290 SQSHRUN, SQSHRUN2

Signed saturating Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see SQRSRUN, SQRSRUN2.

The SQSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer elements = datasize DIV esize;
integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');

**Assembler symbols**

2
Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb>
Is the destination width specifier, encoded in the "immh" field. It can have the following values:

- B when immh = 0001
- H when immh = 001x
- S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d>
Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va>
Is the source width specifier, encoded in the "immh" field. It can have the following values:

- H when immh = 0001
- S when immh = 001x
- D when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.
<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:

• immh = 0000.
• immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
  element = (SInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
  (Elem[result, e, esize], sat) = UnsignedSatQ(element, esize);
  if sat then FPSR.QC = '1';
Vpart[d, part] = result;
C7.2.291  SQSUB

Signed saturating Subtract. This instruction subtracts the element values of the second source SIMD&FP register from the corresponding element values of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.292 SQXTN, SQXTN2

Signed saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates the value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQXTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQXTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
C7.2.295   SRI

Shift Right and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the right of each vector element of the source register are lost.

The following figure shows the operation of shift right by 3 for an 8-bit vector element.

\text{V}[d] = \text{result};
\]
C7.2.296  SRSHL

Signed Rounding Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see SSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\(<V>\) Is a width specifier, encoded in the "size" field. It can have the following values:
- \(D\) when size = 11

The following encodings are reserved:
- size = 0x.
- size = 10.

\(<d>\) Is the number of the SIMD&FP destination register, in the "Rd" field.

\(<n>\) Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\(<m>\) Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

\(<Vd>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<T>\) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- \(8B\) when size = 00, Q = 0
- \(16B\) when size = 00, Q = 1
- \(4H\) when size = 01, Q = 0
- \(8H\) when size = 01, Q = 1
- \(2S\) when size = 10, Q = 0
- \(4S\) when size = 10, Q = 1
- \(2D\) when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

\(<Vn>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);  // 0 for left shift, 2^(n-1) for right shift
    end
    element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elem[result, e, esize] = element<esize-1:0>;
    end

V[d] = result;
```
C7.2.297  SRSHR

Signed Rounding Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, places the final result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are rounded. For truncated results, see SSHR.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Scalar**

\[\text{V[d] = result;}\]
C7.2.299 SSHL

Signed Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts each value by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see SRSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

The encoding immh = 1xxx is reserved.

<vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb>
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift>
Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

The encoding immh = 1xxx is reserved.

2S when im mh = 01xx, Q = 0
4S when im mh = 01xx, Q = 1
2D when im mh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-306 when im mh = 0000, Q = x.

The encoding im mh = 1xxx, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "im mh:im mb" field. It can have the following values:

(128-UInt(im mh:im mb)) when im mh = 1xxx

The encoding im mh = 0xxx is reserved.

For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "im mh:im mb" field. It can have the following values:

(16-UInt(im mh:im mb)) when im mh = 0001
(32-UInt(im mh:im mb)) when im mh = 001x
(64-UInt(im mh:im mb)) when im mh = 01xx
(128-UInt(im mh:im mb)) when im mh = 1xxx

See Advanced SIMD modified immediate on page C4-306 when im mh = 0000.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
  element = (Int(Elem[operand, e, esize], unsigned) + round const) >> shift;
  Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;
V[d] = result;
C7.2.302   SSRA

Signed Shift Right and Accumulate (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see SRSRA.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
[31 30 29 28][27 26 25 24][23 22] [19 18 16|15 14 13 12|11 10 9 | 5 4 | 0 ]

C7.2.303   SSUBL, SSUBL2

Signed Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are twice as long as the source vector elements.

The SSUBL instruction extracts each source vector from the lower half of each source register, while the SSUBL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  if sub_op then
    sum = element1 - element2;
  else
    sum = element1 + element2;
  Elem[result, e, 2*esize] = sum<2*esize-1:0>;
V[d] = result;
```
### C7.2.304 SSUBW, SSUBW2

Signed Subtract Wide. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. All the values in this instruction are signed integer values.

The SSUBW instruction extracts the second source vector from the lower half of the second source register, while the SSUBW2 instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Three registers, not all the same type variant

| $0 | 0 | 1 | 1 | 0 | size | 1 | Rm | 0 | 0 | 1 | 1 | 0 | Rn | Rd |

$Q$ is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when $Q = 0$
- [present] when $Q = 1$

$Vd$ is the name of the SIMD&FP destination register, encoded in the "Rd" field.

$Ta$ is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

$Vn$ is the name of the first SIMD&FP source register, encoded in the "Rn" field.

$Vm$ is the name of the second SIMD&FP source register, encoded in the "Rm" field.

#### Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  - [absent] when $Q = 0$
  - [present] when $Q = 1$

- 8H Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- 4S Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  - 8H when size = 00
  - 4S when size = 01
  - 2D when size = 10

The encoding size = 11 is reserved.

- 8H Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

- 8H Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Tb> is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```
ST1 (multiple structures)

Store multiple single-element structures from one, two, three, or four registers. This instruction stores elements to memory from one, two, three, or four SIMD&FP registers, without interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

boolean wback = TRUE;

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
1D when size = 11, Q = 0
2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
<\texttt{Vt4}> Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

<\texttt{Xn}|\texttt{SP}> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<\texttt{imm}> For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #8 when \texttt{Q} = 0
- #16 when \texttt{Q} = 1

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #16 when \texttt{Q} = 0
- #32 when \texttt{Q} = 1

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #24 when \texttt{Q} = 0
- #48 when \texttt{Q} = 1

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

- #32 when \texttt{Q} = 0
- #64 when \texttt{Q} = 1

<\texttt{Xm}> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

```

Assembler symbols

- `<Vt>` Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1
The encoding size = 11, Q = 0 is reserved.

<\Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<\Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

<\Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<\imm> Is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
#32 when Q = 0
#64 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

C7.2.315  STR (immediate, SIMD&FP)

Store SIMD&FP register (immediate offset). This instruction stores a single SIMD&FP register to memory. The address that is used for the store is calculated from a base register value and an immediate offset.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Post-index**

```
| 31 30 29 28 27 26 25 24 23 22 21 20 | 12 11 10 9 | 5 4 | 0 |
| size | 1 1 1 | 0 0 | x | 0 | 0 | imm9 | 0 | 1 | Rn | Rt |
```

**8-bit variant**

Applies when `size == 00 && opc == 00`.

### Assembler symbols

<\V> Is a width specifier, encoded in the "size" field. It can have the following values:

- D when size = 11
- The following encodings are reserved:
  - size = 0x.
  - size = 10.
<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size-Q" field. It can have the following values:

8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1
The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bthreads(datasize) operand1 = V[n];
bthreads(datasize) operand2 = V[m];
bthreads(datasize) result;
bthreads(esize) element1;
bthreads(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;

V[d] = result;
C7.2.319   **SUBHN, SUBHN2**

Subtract returning High Narrow. This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values.

The results are truncated. For rounded results, see **RSUBHN, RSUBHN2**.

The **SUBHN** instruction writes the vector to the lower half of the destination register and clears the upper half, while the **SUBHN2** instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the **CPACR_EL1, CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

![Instruction encoding](image)

integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');

**Assembler symbols**

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size-Q" field. It can have the following values:

8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- \( 8H \) when \( \text{size} = 00 \)
- \( 4S \) when \( \text{size} = 01 \)
- \( 2D \) when \( \text{size} = 10 \)

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```c
CheckFPAdvSIMDEnabled64();
bv(2*datasize) operand1 = V[n];
bv(2*datasize) operand2 = V[m];
bv(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bv(2*esize) element1;
bv(2*esize) element2;
bv(2*esize) sum;

for e = 0 to elements-1
  element1 = Elem[operand1, e, 2*esize];
  element2 = Elem[operand2, e, 2*esize];
  if sub_op then
    sum = element1 - element2;
  else
    sum = element1 + element2;
  sum = sum + round_const;
  Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```
C7.2.320  SUQADD

Signed saturating Accumulate of Unsigned value. This instruction adds the unsigned integer values of the vector elements in the source SIMD&FP register to corresponding signed integer values of the vector elements in the destination SIMD&FP register, and writes the resulting signed integer values to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SUQADD <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

8 when size = 00
H when size = 01
S when size = 10
D when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(datasize) operand2 = V[d];
integer op1;
integer op2;
boolean sat;

for e = 0 to elements-1
    op1 = Int(Elem[operand, e, esize], !unsigned);
    op2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
    if sat then FPSR.QC = '1';
V[d] = result;
C7.2.321 SXTL, SXTL2

Signed extend Long. This instruction duplicates each vector element in the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SXTL instruction extracts the source vector from the lower half of the source register, while the SXTL2 instruction extracts the source vector from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the SSHLL, SSHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
- The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

Vector variant

is equivalent to

SSHLL[2] <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
25 when \( \text{immh} = 01xx \), \( Q = 0 \)
45 when \( \text{immh} = 01xx \), \( Q = 1 \)

See Advanced SIMD modified immediate on page C4-306 when \( \text{immh} = 0000 \), \( Q = x \).

The encoding \( \text{immh} = 1xxx \), \( Q = x \) is reserved.

**Operation**

The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.
C7.2.322   TBL

Table vector Lookup. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the result for that lookup is 0. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Two register table variant

Applies when len == 01.

TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>

Three register table variant

Applies when len == 10.

TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>

Four register table variant

Applies when len == 11.

TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>

Single register table variant

Applies when len == 00.

TBL <Vd>.<Ta>, { <Vn>.168 }, <Vm>.<Ta>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
   8B when Q = 0
   16B when Q = 1

<Vn> For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.
For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.

\(<\text{Vn}+1>\) Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.

\(<\text{Vn}+2>\) Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.

\(<\text{Vn}+3>\) Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.

\(<\text{Vm}>\) Is the name of the SIMD&FP index register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;
integer i;

// Create table from registers
for i = 0 to regs-1
  table<128*i+127:128*i> = V[n];
  n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
  index = UInt(Elem[indices, i, 8]);
  if index < 16 * regs then
    Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;
```
C7.2.323   TBX

Table vector lookup extension. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the existing value in the vector element of the destination register is left unchanged. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;
C7.2.324 TRN1

Transpose vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

--- Note ---

By using this instruction with TRN2, a 2 x 2 matrix can be transposed.

The following figure shows the operation of TRN1 and TRN2 halfword operations where Q = 0.

![TRN1.16 and TRN2.16 operations](image)

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    Elem[result, e, esize] = Elem[result, e, esize] + absdiff;
V[d] = result;
C7.2.329  **UABDL, UABDL2**

Unsigned Absolute Difference Long. This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, places the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The UABDL instruction extracts each source vector from the lower half of each source register, while the UABDL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

boolean accumulate = (op == '0');
boolean unsigned = (U == '1');

**Assembler symbols**

\(2\)  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent]  when Q = 0
- [present]  when Q = 1

\(<Vd>\)  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<Ta>\)  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H  when size = 00
- 4S  when size = 01
- 2D  when size = 10

The encoding size = 11 is reserved.

\(<Vn>\)  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<Tb>\)  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B  when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<\rm>
Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias(datasize) operand1 = Vpart[n, part];
bias(datasize) operand2 = Vpart[m, part];
bias(2*datasize) result;
integer element1;
integer element2;
bias(2*esize) absdiff;
result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<<esize-1:0;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

C7.2.330 UADALP

Unsigned Add and Accumulate Long Pairwise. This instruction adds pairs of adjacent unsigned integer values from the vector in the source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
    sum = (op1+op2<2*esize-1:0>);
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;
V[d] = result;
C7.2.333   UADDLV

Unsigned sum Long across Vector. This instruction adds every vector element in the source SIMD&FP register
together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as
the source vector elements. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4  | 0 |
|-----------|-----------|-----------|-----------|-----------|-----------|     |
| 0 | Q | 1 | 0 | 1 | 1 | 1 | 0 | size | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | Rd | Rn |   |

Advanced SIMD variant
UADDLV <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 <= UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
H when size = 00
S when size = 01
D when size = 10

The encoding size = 11 is reserved.
<db> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
4S when size = 10, Q = 1

The following encodings are reserved:
• size = 10, Q = 0.
• size = 11, Q = x.
**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer sum;

sum = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    sum = sum + Int(Elem[operand, e, esize], unsigned);

V[d] = sum<2*esize-1:0>;
```
C7.2.334  **UADDW, UADDW2**

Unsigned Add Wide. This instruction adds the vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register. All the values in this instruction are unsigned integer values.

The **UADDW** instruction extracts vector elements from the lower half of the second source register, while the **UADDW2** instruction extracts vector elements from the upper half of the second source register.

Depending on the settings in the **CPACR_EL1, CPTR_EL2, and CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

\[ \text{UADDW}\{2\} \quad \langle Vd\rangle \cdot \langle Ta\rangle, \quad \langle Vn\rangle \cdot \langle Ta\rangle, \quad \langle Vm\rangle \cdot \langle Tb\rangle \]

The encoding size = 11, Q = x is reserved.

**Operation**

```plaintext
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```
C7.2.335 UCVTF (vector, fixed-point)

Unsigned fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar

```
<table>
<thead>

integer esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer fracbits = (esize + 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);

Assembler symbols

<\V> Is a width specifier, encoded in the "immh" field. It can have the following values:
    H when immh = 001x
    S when immh = 01xx
    D when immh = 1xxx
The encoding immh = 000x is reserved.

<\d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<\n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<\Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
    4H when immh = 001x, Q = 0
    8H when immh = 001x, Q = 1
    2S when immh = 01xx, Q = 0
    4S when immh = 01xx, Q = 1
    2D when immh = 1xxx, Q = 1
See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
The following encodings are reserved:
    • immh = 0001, Q = x.
    • immh = 1xxx, Q = 0.

<\n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:
    (32-UInt(immh:immb)) when immh = 001x
    (64-UInt(immh:immb)) when immh = 01xx
    (128-UInt(immh:immb)) when immh = 1xxx
The encoding immh = 000x is reserved.
For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:
    (32-UInt(immh:immb)) when immh = 001x
    (64-UInt(immh:immb)) when immh = 01xx
    (128-UInt(immh:immb)) when immh = 1xxx
See Advanced SIMD modified immediate on page C4-306 when immh = 0000.
The encoding immh = 0001 is reserved.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;
for e = 0 to elements-1
element = Elem[operand, e, esize];
Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);

V[d] = result;
C7.2.336   UCVTF (vector, integer)

Unsigned integer Convert to Floating-point (vector). This instruction converts each element in a vector from an
unsigned integer value to a floating-point value using the rounding mode that is specified by the FPCR, and writes
the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and
Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
    4H when Q = 0
When Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- **2S** when sz = 0, Q = 0
- **4S** when sz = 0, Q = 1
- **2D** when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
FPRounding rounding = FPRoundingMode(FPCR);
bits(esize) element;
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FixedToFP(element, 0, unsigned, FPCR, rounding);
V[d] = result;
```
C7.2.337   UCVTF (scalar, fixed-point)

Unsigned fixed-point Convert to Floating-point (scalar). This instruction converts the unsigned value in the 32-bit or 64-bit general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;
```
case type of 
when '00' fltsize = 32;
when '01' fltsize = 64;
when '10' UnallocatedEncoding();
when '11'
  if HaveFP16Ext() then
    fltsize = 16;
  else
    UnallocatedEncoding();

if sf == '0' && scale<5> == '0' then UnallocatedEncoding();
integer fracbits = 64 - UInt(scale);

rounding = FPRoundingMode(FPCR);

Assembler symbols

<Db> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<SD> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<hn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<fbits> For the 32-bit to double-precision, 32-bit to half-precision and 32-bit to single-precision variant: is the number of bits after the binary point in the fixed-point source, in the range 1 to 32, encoded as 64 minus "scale".
For the 64-bit to double-precision, 64-bit to half-precision and 64-bit to single-precision variant: is the number of bits after the binary point in the fixed-point source, in the range 1 to 64, encoded as 64 minus "scale".

Operation

CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bits(intsize) intval;

intval = X[n];
fltval = FixedToFP(intval, fracbits, TRUE, FPCR, rounding);
V[d] = fltval;
C7.2.338  **UCVTF (scalar, integer)**

Unsigned integer Convert to Floating-point (scalar). This instruction converts the unsigned integer value in the general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 32-bit to half-precision variant

Applies when \( sf == 0 \) \&\& \( type == 11 \).

\[ \text{UCVTF} <Hd>,<Wn> \]

  Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
C7.2.345  UMAXV

Unsigned Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UMAXV <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean min = (op == '1');

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
B when size = 00
H when size = 01
S when size = 10
The encoding size = 11 is reserved.
<db> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
4S when size = 10, Q = 1
The following encodings are reserved:
• size = 10, Q = 0.
• size = 11, Q = x.
Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin-size-1:0;
```
C7.2.346   UMIN

Unsigned Minimum (vector). This instruction compares corresponding vector elements in the two source
SIMD&FP registers, places the smaller of each of the two unsigned integer values into a vector, and writes the
vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

| [31 30 29 28][27 26 25 24][23 22 21 20] | 16|14|13|12|11|10|9 | 5|4|0 |

boolean minimum = (o1 == '1');
```

Assembler symbols

```c
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B  when size = 00, Q = 0
16B when size = 00, Q = 1
4H  when size = 01, Q = 0
8H  when size = 01, Q = 1
2S  when size = 10, Q = 0
4S  when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```c
CheckFPAdvSIMDenabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer maxmin;
```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
C7.2.347 UMINP

Unsigned Minimum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

UMINP `<Vd>.<T>`, `<Vn>.<T>`, `<Vm>.<T>`

#### Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');

#### Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **8B** when size = 00, Q = 0
- **16B** when size = 00, Q = 1
- **4H** when size = 01, Q = 0
- **8H** when size = 01, Q = 1
- **2S** when size = 10, Q = 0
- **4S** when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

#### Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
integer maxmin;

for e = 0 to elements-1
  element1 = Int(Elem[concat, 2*e, esize], unsigned);
  element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);
  maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
  Elem[result, e, esize] = maxmin[size-1:0];

V[d] = result;
C7.2.348   UMINV

Unsigned Minimum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UMINV <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
B when size = 00
H when size = 01
S when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
4S when size = 10, Q = 1

The following encodings are reserved:

* size = 10, Q = 0.
* size = 11, Q = x.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin-esize-1:0;
C7.2.349  **UMLAL, UMLAL2 (by element)**

Unsigned Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLAL instruction extracts vector elements from the lower half of the first source register, while the UMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

\[ \text{UMLAL}\{2\} <\text{Vd}>, <\text{Ta}>, <\text{Vn}>, <\text{Tb}>, <\text{Vm}>, <\text{Ts}>[<\text{index}>] \]

### Decode for this encoding

```plaintext
integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;

case size of
  when '01' index = UInt(H:L:M);
  when '10' index = UInt(H:L);
  otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
```

### Assembler symbols

- **2**  : Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  - [absent] when Q = 0
  - [present] when Q = 1

- **<Vd>**  : Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- **<Ta>**  : Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  - 4S when size = 01
  - 2D when size = 10

The following encodings are reserved:
- size = 00.
• size = 11.

<size>n</size> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

<size>m</size> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

- 0:Rm when size = 01
- M:Rm when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- H:LM when size = 01
- H:L when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1 * element2) < 2*esize-1:0>;
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else
\[ \text{Elem[\text{result, e, 2\times esize}] = Elem[\text{operand3, e, 2\times esize}] + product;} \]

\[ \text{V[d] = result;} \]
C7.2.350 UMLAL, UMLAL2 (vector)

Unsigned Multiply-Add Long (vector). This instruction multiplies the vector elements in the lower or upper half of the first source SIMD&FP register by the corresponding vector elements of the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLAL instruction extracts vector elements from the lower half of the first source register, while the UMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UMLAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
8H when size = 00
4S when size = 01
2D when size = 10
The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<\vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

C7.2.353 UMOV

Unsigned Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (to general). See Alias conditions for details of when each alias is preferred.

32-bit variant

Applies when \( Q = 0 \).

\[
\text{UMOV } <Wd>, <Vn>.<Ts>[<index>] 
\]

64-reg, UMOV-64-reg variant

Applies when \( Q = 1 \) && \( \text{imm5} = x1000 \).

\[
\text{UMOV } <Xd>, <Vn>.<Ts>[<index>] 
\]

Decode for all variants of this encoding

\[
\begin{align*}

& \quad \text{when '0xxx10' size} = 1; \quad \text{// UMOV Wd, Vn.H} \\
& \quad \text{when '0xx100' size} = 2; \quad \text{// UMOV Wd, Vn.S} \\
& \quad \text{when '1x1000' size} = 3; \quad \text{// UMOV Xd, Vn.D} \\
& \quad \text{otherwise UnallocatedEncoding();} \\
\end{align*}
\]

\[
\begin{align*}
\text{integer } \text{idxsize} &= \text{if } \text{imm5}<4> = '1' \text{ then 128 else 64}; \\
\text{integer } \text{index} &= \text{UInt}(\text{imm5}<4:\text{size+1}>); \\
\text{integer } \text{esize} &= 8 << \text{size}; \\
\text{integer } \text{datasize} &= \text{if } Q = '1' \text{ then 64 else 32}; \\
\end{align*}
\]

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (to general)</td>
<td>\text{imm5} = 'x1000'</td>
</tr>
<tr>
<td>MOV (to general)</td>
<td>\text{imm5} = 'xx100'</td>
</tr>
</tbody>
</table>

Assembler symbols

\(<Wd>\)  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xd>\)  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ts> For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

- B when \(imm5 = \text{xxxx1}\)
- H when \(imm5 = \text{xx10}\)
- S when \(imm5 = \text{xx100}\)

The encoding \(imm5 = \text{xx000}\) is reserved.

For the 64-reg,UMOV-64-reg variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

- D when \(imm5 = \text{x1000}\)

The following encodings are reserved:

- \(imm5 = \text{x0000}\).
- \(imm5 = \text{xxxx1}\).
- \(imm5 = \text{xxx10}\).
- \(imm5 = \text{xx100}\).

<index> For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:

- \(imm5<4:1>\) when \(imm5 = \text{xxxx1}\)
- \(imm5<4:2>\) when \(imm5 = \text{xx10}\)
- \(imm5<4:3>\) when \(imm5 = \text{xx100}\)

The encoding \(imm5 = \text{xx000}\) is reserved.

For the 64-reg,UMOV-64-reg variant: is the element index encoded in "imm5<4>".

**Operation**

\[
\text{CheckFPAdvSIMDEnabled64}();
\text{bits(idxsize) operand} = \mathbf{V}[n];
\]

\[
\mathbf{X}[d] = \text{ZeroExtend(Elem[operand, index, esize], datasize)};
\]
C7.2.354 UMULL, UMULL2 (by element)

Unsigned Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMULL instruction extracts vector elements from the lower half of the first source register, while the UMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
Vector variant
UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

Decode for this encoding
integer idxdsz = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
otherwise UnallocatedEncoding();
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 4S when size = 01
- 2D when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

- 0:Rm when size = 01
- M:Rm when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:

- H when size = 01
- S when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:

- H:L:M when size = 01
- H:L when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizel) operand2 = V[m];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = product;

V[d] = result;
```
C7.2.355  UMULL, UMULL2 (vector)

Unsigned Multiply long (vector). This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The **UMULL** instruction extracts each source vector from the lower half of each source register, while the **UMULL2** instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

**UMULL2**  
<Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

**Decode for this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

**Assembler symbols**

2      Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

| absent | when Q = 0 |
| present| when Q = 1 |

<Vd>      Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>      Is an arrangement specifier, encoded in the "size" field. It can have the following values:

| 8H      | when size = 00 |
| 4S      | when size = 01 |
| 2D      | when size = 10 |

The encoding size = 11 is reserved.

<Vn>      Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb>      Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

| 8B      | when size = 00, Q = 0 |
| 16B     | when size = 00, Q = 1 |
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, 2*esize] = (element1*element2)<2*esize-1:0>;

V[d] = result;
```
C7.2.356   UQADD

Unsigned saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Assembler symbols**

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10
D when size = 11

<\d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<\n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<\m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<\Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<\T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<\Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<\Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
boolean sat;

for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  sum = element1 + element2;
  (Elem[result, e, esize], sat) = SatQ(sum, esize, unsigned);
  if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.357  UQRSHL

Unsigned saturating Rounding Shift Left (register). This instruction takes each vector element of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see UQSHL (immediate).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

end
\(V[d] = \text{result};\)
C7.2.358  UQRSHRN, UQRSHRN2

Unsigned saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see UQSHRN, UQSHRN2.

The UQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:
  B when immh = 0001
  H when immh = 001x
  S when immh = 01xx
  D when immh = 1xxx
The encoding immh = 0000 is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
  8B when immh = 0001, Q = 0
  16B when immh = 0001, Q = 1
  4H when immh = 001x, Q = 0
  8H when immh = 001x, Q = 1
  2S when immh = 01xx, Q = 0
  4S when immh = 01xx, Q = 1
  2D when immh = 1xxx, Q = 1
See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

-shift> For the scalar variant: is the left shift amount, in the range 0 to the operand width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
  (UInt(immh:immb)-8) when immh = 0001
  (UInt(immh:immb)-16) when immh = 001x
  (UInt(immh:immb)-32) when immh = 01xx
  (UInt(immh:immb)-64) when immh = 1xxx
The encoding immh = 0000 is reserved.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
  (UInt(immh:immb)-8) when immh = 0001
  (UInt(immh:immb)-16) when immh = 001x
  (UInt(immh:immb)-32) when immh = 01xx
  (UInt(immh:immb)-64) when immh = 1xxx
See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
b工作者 (datasize) operand = \text{V}[n];
b工作者 (datasize) result;
int element;
boolean sat;

for e = 0 to elements-1
    element = \text{Int(\text{Elem}[operand, e, esize, src\_unsigned])} << shift;
    (\text{Elem}[result, e, esize, sat]) = \text{SatQ(element, esize, dst\_unsigned});
    if sat then FPSR.QC = '1';

\text{V}[d] = result;
```
C7.2.360  **UQSHL (register)**

Unsigned saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see **UQRSHL**.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit **FPSR.QC** is set.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);  // 0 for left shift, 2^(n-1) for right shift
        element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```
C7.2.361 UQSHRN, UQSHRN2

Unsigned saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see UQRSHRN, UQRSHRN2.

The UQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Assembler symbols**

2
Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000, Q = x. The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000. The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001
H when immh = 001x
S when immh = 01xx

The following encodings are reserved:
- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<w> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001
S when immh = 001x
D when immh = 01xx
The following encodings are reserved:

- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

\( n \)

Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\( \text{shift} \)

For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

- \( 16\times\text{UInt}(\text{immh}:\text{immb}) \) when \( \text{immh} = 0001 \)
- \( 32\times\text{UInt}(\text{immh}:\text{immb}) \) when \( \text{immh} = 001x \)
- \( 64\times\text{UInt}(\text{immh}:\text{immb}) \) when \( \text{immh} = 01xx \)

The following encodings are reserved:

- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- \( 16\times\text{UInt}(\text{immh}:\text{immb}) \) when \( \text{immh} = 0001 \)
- \( 32\times\text{UInt}(\text{immh}:\text{immb}) \) when \( \text{immh} = 001x \)
- \( 64\times\text{UInt}(\text{immh}:\text{immb}) \) when \( \text{immh} = 01xx \)

See Advanced SIMD modified immediate on page C4-306 when \( \text{immh} = 0000 \).

The encoding \( \text{immh} = 1xxx \) is reserved.

**Operation for all encodings**

\begin{verbatim}
   CheckFPAdvSIMDEnabled64();

V[d] = result;
C7.2.365 URHADD

Unsigned Rounding Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see UHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

URHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<Vd>      Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>      Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
    8B     when size = 00, Q = 0
    16B    when size = 00, Q = 1
    4H     when size = 01, Q = 0
    8H     when size = 01, Q = 1
    2S     when size = 10, Q = 0
    4S     when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.
<Vn>      Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>      Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
C7.2.366   URSHL

Unsigned Rounding Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```
C7.2.371 USHLL, USHLL2

Unsigned Shift Left Long (immediate). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, shifts the unsigned integer value left by the specified number of bits, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The USHLL instruction extracts vector elements from the lower half of the source register, while the USHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias UXTL, UXTL2. See Alias conditions for details of when each alias is preferred.

```

4S  when immh = 01xx, Q = 1
See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<shift>  Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the
"immh:immb" field. It can have the following values:
(UInt(immh:immb)-8)  when immh = 0001
(UInt(immh:immb)-16)  when immh = 001x
(UInt(immh:immb)-32)  when immh = 01xx
See Advanced SIMD modified immediate on page C4-306 when immh = 0000.
The encoding immh = 1xxx is reserved.

Operation

CheckFPAdvSIMDEnabled64();
b ellosize) operand = Vpart[n, part];
b it(sizesize*2) result;
nteger element;

for e = 0 to elements-1
   element = Int(Elem[operand, e, esize], unsigned) << shift;
   Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
C7.2.372 USHR

Unsigned Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see **URSHR**.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Scalar**

```
[31 30 29 28][27 26 25 24][23 22 | 19 18 16|15 14 13 12|11 10 9 | 5 4 | 0 ]
0 1 1 1 1 1 1 0 !=0000 immh 0 0 0 0 0 1 1 Rn Rd
```

**Scalar variant**

if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer shift = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```
Assembler symbols

- `<V>` is a width specifier, encoded in the "immh" field. It can have the following values:
  - D: when immh = 1xxx
  - The encoding immh = 0xxx is reserved.

- `<d>` is the number of the SIMD&FP destination register, in the "Rd" field.

- `<n>` is the number of the first SIMD&FP source register, encoded in the "Rn" field.

- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- `<T>` is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
  - 8B: when immh = 0001, Q = 0
  - 16B: when immh = 0001, Q = 1
  - 4H: when immh = 001x, Q = 0
  - 8H: when immh = 001x, Q = 1
  - 2S: when immh = 01xx, Q = 0
  - 4S: when immh = 01xx, Q = 1
  - 2D: when immh = 1xxx, Q = 1

  See Advanced SIMD modified immediate on page C4-306 when immh = 0000, Q = x.
  - The encoding immh = 1xxx, Q = 0 is reserved.

- `<Vn>` is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<shift>` For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:
  - (128-UInt(immh:immb)) when immh = 1xxx
  - The encoding immh = 0xxx is reserved.

  For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:
  - (16-UInt(immh:immb)) when immh = 0001
  - (32-UInt(immh:immb)) when immh = 001x
  - (64-UInt(immh:immb)) when immh = 01xx
  - (128-UInt(immh:immb)) when immh = 1xxx

  See Advanced SIMD modified immediate on page C4-306 when immh = 0000.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
  element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
  Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;
V[d] = result;
C7.2.373   USQADD

Unsigned saturating Accumulate of Signed value. This instruction adds the signed integer values of the vector elements in the source SIMD&FP register to corresponding unsigned integer values of the vector elements in the destination SIMD&FP register, and accumulates the resulting unsigned integer values with the vector elements of the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
```
C7.2.377  UXTL, UXTL2

Unsigned extend Long. This instruction copies each vector element from the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The **UXTL** instruction extracts vector elements from the lower half of the source register, while the **UXTL2** instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the **CPACR_EL1, CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the **USHLL, USHLL2** instruction. This means that:

- The encodings in this description are named to match the encodings of **USHLL, USHLL2**.
- The description of **USHLL, USHLL2** gives the operational pseudocode for this instruction.

</tr>
</tbody>
</table>

**Vector variant**

**UXTL[2]** `<Vd>.<Ta>`, `<Vn>.<Tb>`

is equivalent to

**USHLL[2]** `<Vd>.<Ta>`, `<Vn>.<Tb>`, #0

and is the preferred disassembly when `BitCount(immh) == 1`.

**Assembler symbols**

2  

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

`<Vd>`  

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`<Ta>`  

Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when `immh = 0001`
- 4S when `immh = 001x`
- 2D when `immh = 01xx`

See *Advanced SIMD modified immediate on page C4-306* when `immh = 0000`. The encoding `immh = 1xxx` is reserved.

`<Vn>`  

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<Tb>`  

Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when `immh = 0001, Q = 0`
- 16B when `immh = 0001, Q = 1`
- 4H when `immh = 001x, Q = 0`
- 8H when `immh = 001x, Q = 1`
25 when immh = 01xx, Q = 0
45 when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

**Operation**

The description of **USHLL**, **USHLL2** gives the operational pseudocode for this instruction.
C7.2.378   UZP1

Unzip vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

--- Note ---
This instruction can be used with UZP2 to de-interleave two vectors.

The following figure shows the operation of UZP1 and UZP2 with the arrangement specifier 8B.

![Figure showing the operation of UZP1 and UZP2]

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Advanced SIMD variant**

UZP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
2D when size = 11, Q = 1
The encoding size = 11, Q = 0 is reserved.

<n> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operandl = V[n];
bits(datasize) operandh = V[m];
bits(datasize) result;
integer e;

bits(datasize*2) zipped = operandh:operandl;
for e = 0 to elements-1
    Elem[result, e, esize] = Elem[zipped, 2*e+part, esize];

V[d] = result;
```
C7.2.379  **UZP2**

Unzip vectors (secondary). This instruction reads corresponding odd-numbered vector elements from the two source SIMD&FP registers, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

--- **Note** ---

This instruction can be used with **UZP1** to de-interleave two vectors.

The following figure shows the operation of **UZP1** and **UZP2** with the arrangement specifier 8B.

![Diagram](image)

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

**UZP2** <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

- integer d = UInt(Rd);
- integer n = UInt(Rn);
- integer m = UInt(Rm);
- if size:Q == '110' then ReservedValue();
- integer esize = 8 << UInt(size);
- integer datasize = if Q == '1' then 128 else 64;
- integer elements = datasize DIV esize;
- integer part = UInt(op);

### Assembler symbols

- <Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1
2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operandl = V[n];
bits(datasize) operandh = V[m];
bits(datasize) result;
integer e;

bits(datasize*2) zipped = operandh:operandl;
for e = 0 to elements-1
    Elem[result, e, esize] = Elem[zipped, 2*e+part, esize];

V[d] = result;
```
C7.2.380  XAR

Exclusive OR and Rotate performs a bitwise exclusive OR of the 128-bit vectors in the two source SIMD&FP registers, rotates each 64-bit element of the resulting 128-bit vector right by the value specified by a 6-bit immediate value, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

ARMv8.2

| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 | 10 9 | 5 4 | 0 |
|----------|----------|----------|----|----|------|----|----|----|
|           |   Rm     |   imm6   |   Rn |   Rd |

Advanced SIMD variant

XAR <Vd>.2D, <Vn>.2D, <Vm>.2D, #<imm6>

Decode for this encoding

if !HaveCryptoExt2() then UnallocatedEncoding();
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

Assembler symbols

<Vd>    Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn>    Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>    Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<imm6>  Is a rotation right, encoded in "imm6".

Operation

bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) tmp;
tmp = Vn EOR Vm;
V[d] = ROR(tmp<127:64>, UInt(imm6)):ROR(tmp<63:0>, UInt(imm6));
C7.2.381 XTN, XTN2

Extract Narrow. This instruction reads each vector element from the source SIMD&FP register, narrows each value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

The XTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the XTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00
4S when size = 01
20 when size = 10

The encoding size = 11 is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, 2*esize];
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```
ZIP1

Zip vectors (primary). This instruction reads adjacent vector elements from the upper half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

--- Note ---
This instruction can be used with ZIP2 to interleave two vectors.

The following figure shows the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

![Operation of ZIP1 and ZIP2](image)

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Advanced SIMD variant**

ZIP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
4S when size = 10, Q = 1
20 when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<n> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer base = part * pairs;
integer p;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, base+p, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, base+p, esize];

V[d] = result;
```
C7.2.383  ZIP2

Zip vectors (secondary). This instruction reads adjacent vector elements from the lower half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

--- Note ---

This instruction can be used with ZIP1 to interleave two vectors.

The following figure shows the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Advanced SIMD variant**

ZIP2 \(<Vd>\., <T>\), \(<Vn>\., <T>\), \(<Vm>\., <T>\)

**Decode for this encoding**

Part D

The AArch64 System Level Architecture
Chapter D1
The AArch64 System Level Programmers’ Model

This chapter describes the AArch64 system level programmers’ model. It contains the following sections:

• Exception levels on page D1-1850.
• Exception terminology on page D1-1851.
• Execution state on page D1-1853.
• Security state on page D1-1854.
• Virtualization on page D1-1856.
• Registers for instruction processing and exception handling on page D1-1859.
• Process state, PSTATE on page D1-1865.
• Program counter and stack pointer alignment on page D1-1868.
• Reset on page D1-1870.
• Exception entry on page D1-1874.
• Exception return on page D1-1883.
• The Exception level hierarchy on page D1-1887.
• Synchronous exception types, routing and priorities on page D1-1894.
• Asynchronous exception types, routing, masking and priorities on page D1-1902.
• Configurable instruction enables and disables, and trap controls on page D1-1910.
• System calls on page D1-1953.
• Mechanisms for entering a low-power state on page D1-1954.
• Self-hosted debug on page D1-1959.
• The Performance Monitors Extension on page D1-1961.
• Interprocessing on page D1-1962.
• The effect of implementation choices on the programmers’ model on page D1-1974.
D1.1 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called unprivileged execution.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

The effect of implementation choices on the programmers’ model on page D1-1974 shows some example implementations.

When executing in AArch64 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the target Exception level of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within a particular Security state. The ARMv8-A security model on page D1-1854 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then when execution is at EL3, the PE can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter D4 The AArch64 Virtual Memory System Architecture.

D1.1.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

<table>
<thead>
<tr>
<th>EL</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Applications</td>
</tr>
<tr>
<td>1</td>
<td>OS kernel and associated functions that are typically described as privileged.</td>
</tr>
<tr>
<td>2</td>
<td>Hypervisor</td>
</tr>
<tr>
<td>3</td>
<td>Secure monitor</td>
</tr>
</tbody>
</table>
D1.2 Exception terminology

The following subsections define the terms used when describing exceptions:

• Terminology for taking an exception.
• Terminology for returning from an exception.
• Exception levels.
• Definition of a precise exception.
• Definitions of synchronous and asynchronous exceptions on page D1-1852.

D1.2.1 Terminology for taking an exception

An exception is generated when the PE first responds to an exceptional condition. The PE state at this time is the state the exception is taken from. The PE state immediately after taking the exception is the state the exception is taken to.

D1.2.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception returns from. The PE state immediately after the execution of that instruction is the state the exception returns to.

D1.2.3 Exception levels

An Exception level, EL<sub>n</sub>, with a larger value of <i>n</i> than another Exception level, is described as being a higher Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of <i>n</i> than another Exception level is described as being a lower Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

• Using AArch64 when execution in that Exception level is in the AArch64 Execution state.
• Using AArch32 when execution in that Exception level is in the AArch32 Execution state.

D1.2.4 Definition of a precise exception

An exception is described as precise when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the SError interrupt, all exceptions taken to AArch64 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch64 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by the instructions can be UNKNOWN, provided that:

• The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
• The registers are not involved in the calculation of the memory address used by the instruction.

Also, for Data Aborts from load or store instructions executed in AArch64 state, where the Data Abort is taken synchronously:

• If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
• If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
• If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.
Examples of instructions that perform more than one single-copy atomic memory access are the AArch32 LDM and STM instructions and the AArch64 LDP and STP instructions.

--- Note ---
For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page B2-89.

D1.2.5 **Definitions of synchronous and asynchronous exceptions**

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

For more information about synchronous exceptions, see Synchronous exception types, routing and priorities on page D1-1894.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about asynchronous exceptions, see Asynchronous exception types, routing, masking and priorities on page D1-1902.
D1.3 Execution state

The Execution states are:

**AArch64** The 64-bit Execution state.

**AArch32** The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

*Execution state on page A1-36* gives more information about them.

Exception levels use Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

--- Note

- *Typical Exception level usage model on page D1-1850* shows which Exception levels different software layers might typically use.

- *The effect of implementation choices on the programmers’ model on page D1-1974* gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing on page D1-1962* describes this.
D1.4 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

Secure state
When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

Non-secure state
When in this state, the PE:
- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see About the Virtual Memory System Architecture (VMSA) on page D4-2082.

D1.4.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.

- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

Security model when EL3 is using AArch64

Figure D1-1 on page D1-1855 shows the security model when EL3 is using AArch64. The figure shows how instances of EL0 and EL1 are present in both Security states. It also shows the expected software usage of the different Exception levels.
Figure D1-1 ARMv8-A security model when EL3 is using AArch64

For an overview of the Security model when EL3 is using AArch32, see Figure G1-1 on page G1-4598.
D1.5 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between virtual machines. A virtual machine comprises Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems. A Guest OS runs on a virtual machine in Non-secure EL1.
- For each Guest operating system, applications, that run on the virtual machine of that Guest OS, usually in Non-secure EL0.

Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a virtual machine identifier (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- Trap various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2. See Configurable instruction enables and disables, and trap controls on page D1-1910.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

ARMv8.1 introduces the Virtualization Host Extensions (VHE) that provide enhanced support for Type 2 hypervisors in Non-secure state. For more information, see Virtualization Host Extensions on page D4-2183.

In Non-secure state, in an implementation that includes EL2:

- The implementation provides an independent translation regime for memory accesses from EL2, the EL2 translation regime. An implementation that includes ARMv8.1-VHE also supports an alternative EL2&0 translation regime.

Note

An implementation that includes ARMv8.1-VHE can be configured so that the EL2&0 translation regime is used both for accesses from EL2 and for accesses from Non-secure EL0.

- For the EL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the virtual address (VA) to an intermediate physical address (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the physical address (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

- When ARMv8.3-NV is implemented, a Guest Hypervisor can be run at EL1. For more information on how this affects address translation, see Nested virtualization on page D4-2188.

For more information on the translation regimes, see Chapter D4 The AArch64 Virtual Memory System Architecture.
D1.5.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. *EL2 configurable controls on page D1-1920*, describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

Hypervisor call exceptions taken from EL3 are taken to EL3. Otherwise, Hypervisor call exceptions are taken from Non-secure state to EL2.

All virtual interrupts are always taken to Non-secure EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See *Virtual interrupts*.

When a virtual interrupt is enabled, in Non-secure state its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3.

For more information, see *Asynchronous exception types, routing, masking and priorities on page D1-1902*.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information, see:
  - *Routing exceptions from Non-secure EL0 to EL2 on page D1-1895*.
  - *Routing debug exceptions on page D2-1985*.
- Provides mechanisms to trap Non-secure PE operations to EL2. See *EL2 configurable controls on page D1-1920*.
  When an operation is trapped to EL2, the hypervisor typically either:
  - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  - Returns an error to the Guest OS.

**Virtual interrupts**

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table D1-1.

<table>
<thead>
<tr>
<th>Physical interrupt</th>
<th>Corresponding virtual interrupt</th>
</tr>
</thead>
<tbody>
<tr>
<td>SError</td>
<td>Virtual SError</td>
</tr>
<tr>
<td>IRQ</td>
<td>Virtual IRQ</td>
</tr>
<tr>
<td>FIQ</td>
<td>Virtual FIQ</td>
</tr>
</tbody>
</table>

Software executing in EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. Example D1-1 on page D1-1858 shows a usage model for virtual interrupts.
Example D1-1 Virtual interrupt usage model

A virtual interrupt usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.

2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

A hypervisor can prevent Non-secure EL1 and Non-secure EL0 from distinguishing a virtual interrupt from a physical interrupt.

- *Asynchronous exception types, routing, masking and priorities* on page D1-1902.
- *Virtual interrupts* on page D1-1907.
D1.6 Registers for instruction processing and exception handling

In the ARM architecture, registers fall into two main categories:

- Registers that provide system control or status reporting. These are described in Chapter D10 AArch64 System Register Descriptions.
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions. This section introduces these registers, for execution in AArch64 state.

This section contains the following subsections:

- The general purpose registers, R0-R30.
- The stack pointer registers.
- The SIMD and floating-point registers, V0-V31 on page D1-1860.
- Saved Program Status Registers (SPSRs) on page D1-1860.
- Exception Link Registers (ELRs) on page D1-1864.

D1.6.1 The general purpose registers, R0-R30

The general purpose register bank is used when processing instructions in the base instruction set. It comprises 31 general purpose registers, R0-R30.

These registers can be accessed as 31 64-bit registers, X0-X30, or 31 32-bit registers, W0-W30. See Register size on page C6-524.

For information on the format of these registers, see Registers in AArch64 state on page B1-77.

D1.6.2 The stack pointer registers

In AArch64 state, in addition to the general purpose registers, a dedicated stack pointer register is implemented for each implemented Exception level. The stack pointer registers are:

- SP_EL0 and SP_EL1.
- If the implementation includes EL2, SP_EL2.
- If the implementation includes EL3, SP_EL3.

Note

The four stack pointer register names define an architecture state requirement for four registers. For information on how to access these registers, and access restrictions, see Special-purpose registers on page C5-339.

For information on stack pointer alignment restrictions, see SP alignment checking on page D1-1868.

Stack pointer register selection

When executing at EL0, the PE uses the EL0 stack pointer, SP_EL0.

When executing at any other Exception level, the PE can be configured to use either SP_EL0 or the stack pointer for that Exception level, SP_ELx.

By default, taking an exception selects the stack pointer for the target Exception level, SP_ELx. For example, taking an exception to EL1 selects SP_EL1. Software executing at the target Exception level can then choose to change the stack pointer to SP_EL0 by updating PSTATE.SP.

This applies even if taking the exception does not change the Exception level. For example, if the PE is executing at EL1 and the PE is using the SP_EL0 stack pointer, then on taking an exception that targets EL1, the stack pointer changes to SP_EL1.

The selected stack pointer can be indicated by a suffix to the Exception level:

- t Indicates use of the SP_EL0 stack pointer.
- h Indicates use of the SP_ELx stack pointer.
D1.6 Registers for instruction processing and exception handling

--- Note ---

The t and h suffixes are based on the terminology of thread and handler, introduced in ARMv7-M.

---

Table D1-2 shows the set of stack pointer options.

<table>
<thead>
<tr>
<th>Exception level</th>
<th>AArch64 stack pointer options</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>EL0t</td>
</tr>
<tr>
<td>EL1</td>
<td>EL1t, EL1h</td>
</tr>
<tr>
<td>EL2</td>
<td>EL2t, EL2h</td>
</tr>
<tr>
<td>EL3</td>
<td>EL3t, EL3h</td>
</tr>
</tbody>
</table>

---

D1.6.3 The SIMD and floating-point registers, V0-V31

The SIMD and floating-point instructions share a common bank of registers for floating-point, vector, and other SIMD-related scalar operations.

The SIMD and floating-point register bank comprises 32 quadword (128-bit) registers, V0-V31.

These registers can be accessed as:

- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.

For information on the format of these registers, see Registers in AArch64 state on page B1-77.

---

D1.6.4 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions.

In AArch64 state, there is an SPSR at each Exception level exceptions can be taken to, as follows:

- SPSR_EL1, for exceptions taken to EL1 using AArch64.
- If EL2 is implemented, SPSR_EL2, for exceptions taken to EL2 using AArch64.
- If EL3 is implemented, SPSR_EL3, for exceptions taken to EL3 using AArch64.

--- Note ---

Exceptions cannot be taken to EL0.

---

When the PE takes an exception, the PE state is saved from PSTATE in the SPSR at the Exception level the exception is taken to. For example, if the PE takes an exception to EL1, the PE state is saved in SPSR_EL1. For more information on PSTATE, see Process state, PSTATE on page D1-1865.

Saving the PE state means the exception handler can:

- On return from the exception, restore the PE state to the state stored in the SPSR at the Exception level the exception is returning from. For example, on returning from EL1, the PE state is restored to the state stored in SPSR_EL1.
- Examine the value that PSTATE had when the exception was taken, for example to determine the Execution state and Exception level in which the instruction that caused an exception was executed.
Note

- All PSTATE fields are saved, including those which have no direct read and write access, and those that are meaningful only in AArch32 state.
- Those PSTATE fields that are meaningful only in AArch32 state are saved when an exception is taken from AArch32 state to AArch64 state.

The SPSRs are unknown on reset.

SPSR format for exceptions taken to AArch64 state

Exceptions can be taken to AArch64 state from AArch64 state or AArch32 state:

- For an exception taken to AArch64 state from AArch64 state, the SPSR bit assignments are:

  | 31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
  |--------|--------|--------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
  |  N  |  Z  |  C  |  V  | RES0 | RES0 |  M[3:0] |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
  | N, Z, C, V, bits[31:28] |
  | Shows the values of the PSTATE. {N, Z, C} Condition flags immediately before the exception was taken. |

- For an exception taken to AArch64 state from AArch32 state, the SPSR bit assignments are:

  | 31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
  |--------|--------|--------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
  | N, Z, C, V, bits[31:28] |
  | Shows the values of the PSTATE. {N, Z, C} Condition flags immediately before the exception was taken. |

  | 31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
  |--------|--------|--------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
  |  IL  |  SS  | PAN, from ARMv8.1 | UAO, from ARMv8.2 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
  | Mask bits |
  | M[4], Execution State |

The following list describes the bit assignments:

N, Z, C, V, bits[31:28]

  Shows the values of the PSTATE. {N, Z, C} Condition flags immediately before the exception was taken.

Bits[27:24], for exceptions taken from AArch64 state

  Reserved, RES0.

Q, bit[27], for exceptions taken from AArch32 state

  Shows the value of PSTATE.Q immediately before the exception was taken.

IT[1:0], bits[26:25], for exceptions taken from AArch32 state

  See IT[7:2] on page D1-1862.

J, bit[24], for exceptions taken from AArch32 state

  Shows the value of PSTATE.J immediately before the exception was taken. This bit is RES0.

UAO, bit[23], from ARMv8.2

  Shows the value of PSTATE.UAO immediately before the exception was taken.

  This bit is RES0 in ARMv8.0 and in ARMv8.1 when ARMv8.2-UAO is not implemented.
PAN, bit[22], from ARMv8.1
Shows the value of PSTATE.PAN immediately before the exception was taken.
This bit is RES0 when ARMv8.1-PAN is not implemented.

SPSR_ELx.SS is used by a debugger to initiate a Software Step exception. The SS bit also indicates
which software step state machine state the PE was in. See Software Step exceptions on
page D2-2032.

IL, bit[20]  Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was
taken. See Illegal return events from AArch64 state on page D1-1884.

Bits[19:10], for exceptions taken from AArch64 state
Reserved, RES0.

GE[3:0], bits [19:16], for exceptions taken from AArch32 state
Shows the value of PSTATE.GE immediately before the exception was taken.

IT[7:2], bits [15:10], for exceptions taken from AArch32 state
With IT[1:0] on page D1-1861, shows the value of PSTATE.IT before the exception was taken.

D, bit[9], for exceptions taken from AArch64 state
The debug exception mask bit. Shows the value of PSTATE.D immediately before the exception
was taken. See The PSTATE debug mask bit, D on page D1-1959.

E, bit[9], for exceptions taken from AArch32 state
Endianness of data accesses. Shows the value of PSTATE.E immediately before the exception was
taken.

A, I, F, bits[8:6]
Shows the values of the PSTATE.{A, I, F} exception mask bits immediately before the exception
was taken:
See Asynchronous exception masking on page D1-1905.

Bit[5], for exceptions taken from AArch64 state
Reserved, RES0.

T, bit[5], for exceptions taken from AArch32 state
Shows the value of PSTATE.T immediately before the exception was taken.

M[4:0], bits[4:0], for exceptions taken from AArch64 state

Note
The name of this field is inherited from ARMv7, where the M field specified the PE mode.

M[4]  The value of this is 0. M[4] encodes the value of PSTATE.nRW, that indicates the
Execution state from which the exception was taken.
M[3:0]  Encodes the Exception level and the stack pointer register selection, as shown in Table D1-3.

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Exception level and stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>EL.3h</td>
</tr>
<tr>
<td>0b1110</td>
<td>EL.3t</td>
</tr>
<tr>
<td>0b1101</td>
<td>EL.2h</td>
</tr>
<tr>
<td>0b1000</td>
<td>EL.2t</td>
</tr>
<tr>
<td>0b0101</td>
<td>EL.1h</td>
</tr>
<tr>
<td>0b0100</td>
<td>EL.1t</td>
</tr>
<tr>
<td>0b0000</td>
<td>EL.0t</td>
</tr>
</tbody>
</table>

a. All M[3:0] encodings not shown in the table are reserved.

The M[3:0] encoding comprises:
- M[1]   Reserved, RES0. If set to 1 at the time of an exception return, then that exception return is treated as an Illegal Execution state exception return.
- M[0]   Selects the SP:
  - 0  SP_EL0. Indicated by a t suffix on the Exception level.
  - 1  SP_ELx, where x is the value of M[3:2]. Indicated by an h suffix on the Exception level.

See Stack pointer register selection on page D1-1859.

M[4:0], bits[4:0], for exceptions taken from AArch32 state

The Mode field. Specifies the AArch32 PE mode.

- M[4]   The value of this is 1. M[4] encodes the value of PSTATE.nRW, that indicates the Execution state from which the exception was taken.
- M[3:0]  Encodes the AArch32 PE mode that the PE was in immediately before the exception was taken, as shown in Table D1-4.

Table D1-4 M[3:0] encodings, for exceptions taken from AArch32 state

<table>
<thead>
<tr>

</tbody>
</table>
Note

In this description of SPSR:
• For exceptions taken from AArch64 state, PSTATE links to the AArch64 system level description.
• For exceptions taken from AArch32 state, PSTATE links to the AArch32 system level description.

SPSR bits:
• That are defined as RES0 on an exception taken from AArch32 state are ignored on any exception return to AArch32 state.
• That are defined as RES0 on an exception taken from AArch64 state are ignored on any exception return to AArch64 state.

Pseudocode description of SPSR operations

The SPSR[] pseudocode function accesses the current SPSR, and is common to AArch32 and AArch64 operations. The SetPSTATEFromPSR() pseudocode function updates PSTATE from an SPSR.

D1.6.5 Exception Link Registers (ELRs)

Exception Link Registers hold preferred exception return addresses.

Whenever the PE takes an exception, the preferred return address is saved in the ELR at the Exception level the exception is taken to. For example, whenever the PE takes an exception to EL1, the preferred return address is saved in ELR_EL1.

On an exception return, the PC is restored to the address stored in the ELR. For example, on returning from EL1, the PC is restored to the address stored in ELR_EL1.

AArch64 state provides an ELR for each Exception level exceptions can be taken to. The ELRs that AArch64 state provides are:
• ELR_EL1, for exceptions taken to EL1.
• If EL2 is implemented, ELR_EL2, for exceptions taken to EL2.
• If EL3 is implemented, ELR_EL3, for exceptions taken to EL3.

On taking an exception from AArch32 state to AArch64 state, bits[63:32] of the ELR are set to zero.

The preferred return address depends on the nature of the exception. For more information, see Preferred exception return address on page D1-1875.
D1.7 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:
- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type ProcState. ProcState is defined in Chapter J1 ARMv8 Pseudocode.

The PSTATE fields that are meaningful in AArch64 state are:

The Condition flags

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Negative Condition flag.</td>
</tr>
<tr>
<td>Z</td>
<td>Zero Condition flag.</td>
</tr>
<tr>
<td>C</td>
<td>Carry Condition flag.</td>
</tr>
<tr>
<td>V</td>
<td>Overflow Condition flag.</td>
</tr>
</tbody>
</table>

Process state, PSTATE on page B1-79 gives more information about these flags.

The Execution state controls

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SS</td>
<td>Software Step bit, see Software Step exceptions on page D2-2032. On a reset or taking an exception to AArch64 state, this bit is set to 0.</td>
</tr>
<tr>

<td>Illegal Execution state bit, see The Illegal Execution state exception on page D1-1886. On a reset or taking an exception to AArch64 state, this bit is set to 0.</td>
</tr>
<tr>
<td>nRW</td>
<td>Current Execution state, see Execution state on page D1-1853. This bit is 0 when the current Execution state is AArch64. This bit is set to 0:</td>
</tr>
<tr>
<td></td>
<td>• On reset into an Exception level that is using AArch64.</td>
</tr>
<tr>
<td></td>
<td>• On taking an exception to an Exception level that is using AArch64.</td>
</tr>
<tr>
<td>EL</td>
<td>Current Exception level, see Exception levels on page D1-1850. On a reset to AArch64 state, this field holds the encoding for the highest implemented Exception level.</td>
</tr>
</tbody>
</table>

Note

The ARM architecture requires that a PE resets into the highest implemented Exception level.

SP Stack pointer register selection bit, see Stack pointer register selection on page D1-1859. On a reset or taking an exception to AArch64 state, this bit is set to 1, meaning that SP_ELx is selected.

The exception mask bits

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Debug exception mask bit, see The PSTATE debug mask bit, D on page D1-1959. On a reset or taking an exception to AArch64 state, this bit is set to 1.</td>
</tr>
<tr>
<td>A, I, F</td>
<td>Asynchronous exception mask bits:</td>
</tr>
<tr>
<td></td>
<td>• SError interrupt mask bit.</td>
</tr>
<tr>
<td></td>
<td>• IRQ interrupt mask bit.</td>
</tr>
<tr>
<td></td>
<td>• FIQ interrupt mask bit.</td>
</tr>
</tbody>
</table>

See Asynchronous exception types, routing, masking and priorities on page D1-1902. On a reset or taking an exception to AArch64 state, each of these bits is set to 1.
Access control bits

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

<td>Privileged Access Never (PAN) state bit. For more information, see About PSTATE.PAN on page D4-2156. This bit is implemented only when ARMv8.1-PAN is implemented.</td>
</tr>
<tr>
<td>UAO</td>
<td>User Access Override (UAO) bit. For more information, see About PSTATE.UAO on page D4-2157. This bit is implemented only when ARMv8.2-UAO is implemented.</td>
</tr>
</tbody>
</table>

**D1.7.1 Accessing PSTATE fields**

In AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the MRS instruction, and directly written using the MSR (register) instructions. Table D1-5 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state, when the PE is in AArch64 state. All other PSTATE fields do not have direct read and write access.

**Table D1-5 Accessing PSTATE fields using MRS and MSR (register)**

<table>
<thead>
<tr>
<th>Special-purpose register</th>
<th>PSTATE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>NZCV</td>
<td>N, Z, C, V</td>
</tr>
<tr>
<td>DAIF</td>
<td>D, A, I, F</td>
</tr>

<tr>
<td>DAIFClr</td>
<td>D, A, I, F</td>
<td>Directly clears any of the PSTATE. {D, A, I, F} bits to 0</td>
</tr>
<tr>
<td>SPSel</td>
<td>SP</td>
<td>Directly sets PSTATE.SP to either 1 or 0</td>
</tr>
<tr>
<td>PAN</td>
<td>PAN</td>
<td>Directly sets PSTATE.PAN to either 1 or 0</td>
</tr>
<tr>
<td>UAO</td>
<td>UAO</td>
<td>Directly sets PSTATE.UAO to either 1 or 0</td>
</tr>
</tbody>
</table>

PSTATE. {N, Z, C, V} can be accessed at EL0. Access to PSTATE. {D, A, I, F} at EL0 using AArch64 depends on SCTLR_EL1.UMA, see Traps to EL1 of EL0 accesses to the PSTATE. {D, A, I, F} interrupt masks on page D1-1914. All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.
D1.7.2   The Saved Program Status Registers (SPSRs)

On taking an exception, PSTATE is preserved in the SPSR of the Exception level the exception is taken to. The
SPSRs are described in *Saved Program Status Registers (SPSRs)* on page D1-1860.
D1.8 Program counter and stack pointer alignment

This section contains the following:

- PC alignment checking.
- SP alignment checking.

D1.8.1 PC alignment checking

PC alignment checking generates a PC alignment fault exception associated with the instruction fetch if, in AArch64 state, there is an attempt to architecturally execute an instruction that was fetched with a misaligned PC. A misaligned PC is when bits[1:0] of the PC are not 0b00.

Note

As with Instruction Aborts, speculative fetching of an instruction does not generate an exception. An exception occurs only on an attempt to architecturally execute the instruction.

If an exception is generated as a result of an instruction fetch at EL0, it is taken to EL1, unless the exception occurs in Non-secure state and HCR_EL2.TGE bit is 1, when it is taken to EL2 instead. If an exception is generated as a result of an instruction fetch at any other Exception level, the Exception level is unchanged.

A PC misalignment sets the EC field in the Exception Syndrome Register (ESR) to 0x22, for the ESR associated with the target Exception level.

When the exception is taken to an Exception level using AArch64, the associated Exception Link Register holds the entire PC in its misaligned form, as does the FAR_ELx for the Exception level that the exception is taken to.

Exception return and PC alignment on page D1-1884 gives more information on PC alignment checking associated with exception returns.

Note

A misalignment of the PC is a common indication of a serious error, for example software corruption of an address.

The pseudocode function AArch64.CheckPCAlignment() performs PC alignment checking in AArch64 state. When necessary it calls AArch64.PCAlignmentFault() to generate an exception.

D1.8.2 SP alignment checking

A misaligned stack pointer is where bits[3:0] of the stack pointer are not 0b0000, when the stack pointer is used as the base address of the calculation, regardless of any offset applied by the instruction.

The PE can be configured so that if a load or store instruction uses a misaligned stack pointer, the PE generates an SP alignment fault exception on the attempt to execute the instruction. In this configuration, CheckSPAlignment() performs the stack pointer check, and calls AArch64.SPAlignmentFault() if a misaligned stack pointer is found.

Note

- As with Data Aborts, a speculative data access to memory using the stack pointer does not generate the exception. The exception occurs only on an attempt to architecturally execute the instruction.
- Prefetch memory abort instructions do not cause synchronous exceptions. See Prefetch memory on page C3-180.

Stack pointer alignment checking is only performed in AArch64 state, and can be enabled for each Exception level as follows:

- SCTLR_EL1.{SA0, SA} controls EL0 and EL1, respectively
- SCTLR_EL2.SA controls EL2
- SCTLR_EL3.SA controls EL3.
If an exception is generated as a result of a load or store at EL0, it is taken as an exception to EL1 unless the HCR_EL2.TGE bit is set in the Non-secure state, when it is taken to EL2. If an exception is generated as a result of a load or store at any other Exception level, the Exception level is unchanged.

A stack pointer misalignment sets the EC field to 0x26, in the ESR associated with the target Exception level. If memory alignment checking and stack pointer alignment checking are enabled, then an SP alignment fault has priority in setting the value of the EC field, in the ESR associated with the target Exception level.

The pseudocode function CheckSPAlignment() performs the stack pointer alignment check. When necessary it calls AArch64.SPAlignmentFault() to generate an exception.
D1.9  Reset

The ARMv8-A architecture supports the following resets:

**Cold reset**
- Resets all of the logic on which the PE executes, including the integrated debug functionality.
- In some contexts, this logic is described as belonging to the *Cold reset domain*.

**Warm reset**
- Resets the logic on which the PE executes, but does not reset the integrated debug functionality.
- In some contexts, this logic is described as belonging to the *Warm reset domain*.

--- Note

The ARMv8-A architecture also supports an external debug reset. See *External debug register resets on page H8-5835*.

The difference between a Cold reset and a Warm reset is relevant only to the debug functionality and the RMR_ELx register, if an RMR_ELx register is implemented:
- A Warm reset permits debugging across a reset of the PE logic.
- Writing 1 to RMR_ELx.RR requests a Warm reset.

The mechanisms, other than RMR_ELx.RR, to assert these resets are IMPLEMENTATION DEFINED. It is IMPLEMENTATION DEFINED whether:
- It is possible to independently assert an External Debug reset and a Cold reset.
- It is possible to assert a Warm reset, as opposed to asserting a Cold reset, other than by the use of RMR_ELx.RR.

--- Note

ARM recommends that:
- If separate Core and Debug power domains are implemented, as described in *Reset and debug on page H6-5809*, then a Cold reset can be asserted independently of External Debug reset.
- A Warm reset can be asserted to permit debugging across a reset of the PE logic.

This means that an implementation can define other resets according to the requirements the implementation or system must fulfil. These other resets are outside the scope of the ARMv8-A architecture. However, they can be mapped onto the resets described here.

In the description that follows, the term *reset* is used in contexts where there is no difference between the effect of a Cold reset and the effect of a Warm reset.

On a reset, the PE enters the highest implemented Exception level.

If the highest implemented Exception level can use either Execution state, then:
- The implementation must include a *Reset Management Register* (RMR). Only one RMR is implemented. The RMR implemented is the RMR is associated with the highest Exception level.
- On a Cold reset, the Execution state entered is determined by a configuration input signal.
- On a Warm reset, the Execution state entered is determined by RMR_ELx.AA64.

If the highest implemented Exception level is configured to use AArch64 state, then on reset:
- The stack pointer for the highest implemented Exception level, SP_ELx, is selected.
- Execution starts at an IMPLEMENTATION DEFINED address, anywhere in the physical address range. The RVBAR associated with the highest implemented Exception level, RVBAR_EL1, RVBAR_EL2, or RVBAR_EL3, holds this address.
The remainder of this section contains the following:

- **PE state on reset to AArch64 state.**
- **Code sequence to use RMR_ELx.RR to request a Warm reset on page D1-1873.**

For more information about reset see:

- **Behavior of caches at reset on page D3-2057.**
- **TLB behavior at reset on page D4-2205.**
- **Reset and debug on page H6-5809.**

## D1.9.1 PE state on reset to AArch64 state

--- **Note** ---

See the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* for the reset requirements for GIC System registers.

---

Immediately after a reset, much of the PE state is UNKNOWN. However, some of the PE state is defined. If the PE resets to AArch64 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- Each of the PSTATE.{D, A, I, F} interrupt masks is set to 1.
- The Software step control bit, PSTATE.SS, is set to 0.
- The IL process state bit, PSTATE.IL, is set to 0.
- All general-purpose, and SIMD and floating-point registers are UNKNOWN.
- The ELR and SPSR for each Exception level are UNKNOWN.
- The stack pointer register for each Exception level is UNKNOWN.
- The global exclusive monitor and local exclusive monitor for the PE are UNKNOWN.
- Unless explicitly defined in this subsection, each System register at each Exception level is in an architecturally UNKNOWN state.
- The TLBs and caches are in an IMPLEMENTATION DEFINED state. This means that the TLBs, the caches, or both, might require invalidation using IMPLEMENTATION DEFINED invalidation sequences before the memory management system is enabled or Normal memory accesses are permitted to be Cacheable.

--- **Note** ---

- On reset, System register Cacheability control fields force all Normal memory accesses to be treated as Non-cacheable. This applies only for the translation regime used by the Exception level and Security state entered on reset. For information about these controls see *Enabling and disabling the caching of memory accesses on page D3-2055.*
- The implementation might include IMPLEMENTATION DEFINED resets. If it does, each of these resets might treat the cache and TLB state differently. The ARMv8-A architecture permits this.
- Different IMPLEMENTATION DEFINED invalidation sequences might be required for different IMPLEMENTATION DEFINED resets.
- In some implementations, the IMPLEMENTATION DEFINED invalidation sequence might be aNOP.

- In the SCTLR_ELx for the highest implemented Exception level:
  - Each of the {M, C, I} bits is set to 0
  - The EE bit is set to an IMPLEMENTATION DEFINED value, typically defined by a configuration input.

- If an RMR is implemented, RMR_ELx.RR is set to 0. ELx in this context is the highest implemented Exception level.
The enables for the counter event stream are set to 0. This means that the following bits are set to 0:
- CNTKCTL_EL1.EVNTEN.
- If the implementation includes EL2, CNTHCTL_EL2.EVNTEN.

PMCR_EL0.E is set to 0.

--- Note ---
This means the Performance Monitors cannot assert interrupts at reset.

OSDLR_EL1.DLK bit is set to 0.

Each of MDCCINT_EL1.{TX, RX} is set to 0.

EDPRCR.CWRR is set to 0.

EDPRESR.SR is set to 1.

If the implementation includes EL3, then each of MDCR_EL3.{EPMAD, EDAD, SPME} is set to 0.

If the implementation includes EL2, then MDCR_EL2.HPMN is set to the value of PMCR_EL0.N.

EDESR.OSUC is set to 0, and EDESR.{SS, RC} are set to the values of EDECR.{SS, RCE}.

--- Note ---
On an External debug reset, EDECR.{SS, RCE} are set to 0.

Additionally, for a Cold reset into AArch64 state:

If an RMR is implemented, RMR_ELx.AA64 is set to 1. ELx in this context is the highest implemented Exception level.

Each of MDCCSR_EL0.{TXfull, RXfull} is set to 0.

The DBGPRCR_EL1.COREPRDRQ is set to the value of EDPRCR.COREPURQ. An External Debug reset sets EDPRCR.COREPURQ to 0, see External debug register resets on page H8-5835. If an External Debug reset and a Cold reset coincide, both DBGPRCR_EL1.COREPRDRQ and EDPRCR.COREPURQ are reset to 0.

The debug CLAIM bits are reset to 0.

--- Note ---
These are the bits that are set to 1 by writing to DBGCLAIMSET_EL1.CLAIM, and cleared to 0 by writing to DBGCLAIMCLR_EL1.CLAIM.

Each of EDSCR.{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} is set to 0.

--- Note ---
MDCCSR_EL0.{RXfull, TXfull} reflect the values in EDSCR.{RXfull, TXfull}.

Each of EDECCR.{NSE, SE} is set to 0.

OSLSR_EL1.OSLK is set to 1.

In the EDPRESR:
- The SPMAD, SDAD fields are set to 0.
- The SPD field is set to 1.
### D1.9.2 Code sequence to use RMR_ELx.RR to request a Warm reset

The following assembler sequence uses RMR_ELx.RR to request a Warm reset:

```assembly
; in addition, interrupts and debug requests for this PE should be disabled
; in the system before running this sequence to ensure the WFI suspends execution
MOV Wy, #3        ; for AArch64, #2 for AArch32; y is any register
DSB               ; ensure all stores etc are complete
MSR RMR_ELx, Wy   ; request the reset
ISB               ; synchronise change to the RMR
Loop
  WFI           ; enter a quiescent state
  B Loop
```

### D1.9.3 Pseudocode description of reset

The `AArch64.TakeReset()` pseudocode function performs a reset into AArch64 state.

`AArch64.TakeReset()` calls the functions `AArch64.ResetGeneralRegisters()`, `AArch64.ResetSIMDFPRegisters()`, `AArch64.ResetSpecialRegisters()`, `AArch64.ResetSystemRegisters()`, and `ResetExternalDebugRegisters()`.

`AArch64.ResetSystemRegisters()` resets all System registers to their reset state as defined in the register descriptions in *PE state on reset to AArch64 state* on page D1-1871 and Chapter D10 *AArch64 System Register Descriptions*.

---

**Note**

The `AArch64.ResetSystemRegisters()` function only resets the System registers.

---

`ResetExternalDebugRegisters()` resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 *External Debug Register Descriptions*.  

---
D1.10 Exception entry

Exceptions are targeted at particular Exception levels. The Exception level that an exception targets is either programmed by software, or is determined by the nature of the exception.

Under no circumstances do exceptions cause execution to move to a lower Exception level.

If an asynchronous exception targets a lower Exception level, the exception is not taken and remains pending. See *Asynchronous exception routing* on page D1-1903 and *Asynchronous exception masking* on page D1-1905.

Note

The construction of the architecture means that usually, it is impossible for an exception to target a lower Exception level.

The Security state can only change on taking an exception if the exception is taken from Non-secure state to EL3.

Note

Taking an exception to EL3 from any Exception level has no effect on the value of the SCR_EL3.NS bit.

On taking an exception to AArch64 state:

- The PE state is saved in the SPSR_ELx at the target Exception level. See *Saved Program Status Registers (SPSRs)* on page D1-1860.
- The preferred return address is saved in the ELR_ELx at the target Exception level. See *Exception Link Registers (ELRs)* on page D1-1864.
- All of PSTATE.{D, A, I, F} are set to 1. See *Process state, PSTATE* on page D1-1865.
- If ARMv8.2-UAO is implemented, PSTATE.UAO is set to 0. See *Process state, PSTATE* on page D1-1865.
- If the exception is a synchronous exception or an SErr or interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the target Exception level. See *Use of the ESR_EL1, ESR_EL2, and ESR_EL3* on page D1-1876.
- The stack pointer register selected is the dedicated stack pointer register for the target Exception level. See *The stack pointer registers* on page D1-1859.
- For a physical SErr interrupt exception, if the SErr interrupt is edge-triggered, the pending state of the physical SErr is cleared.
- For a virtual SErr interrupt exception, the pending state of the virtual SErr, held in the HCR_EL2.VSE bit, is cleared. See *Virtual interrupts* on page D1-1907.
- If ARMv8.2-IESB is implemented, when the SCTLR_ELx.IESB bit at the target Exception level is 1, the PE inserts an error synchronization event. See *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.
- Execution moves to the target Exception level, and starts at the address defined by the exception vector. Which exception vector is used is also an indicator of whether the exception came from a lower Exception level or the current Exception level. See *Exception vectors* on page D1-1875.

The remainder of this section contains the following:

- *Preferred exception return address* on page D1-1875.
- *Exception vectors* on page D1-1875.
- *Pseudocode description of exception entry to AArch64 state* on page D1-1876.
- *Exception classes and the ESR_ELx syndrome registers* on page D1-1876.
- *Summary of register updates on faults taken to an Exception level that is using AArch64* on page D1-1881.
D1.10.1 Preferred exception return address

For an exception taken to an Exception level using AArch64, the Exception Link Register for that Exception level, ELR_ELx, holds the preferred exception return address. The preferred exception return address depends on the nature of the exception, as follows:

- For asynchronous exceptions, it is the address of the instruction following the instruction boundary at which the interrupt occurs. Therefore, it is the address of the first instruction that did not execute, or did not complete execution, as a result of taking the interrupt.
- For synchronous exceptions other than system calls, it is the address of the instruction that generates the exception.
- For exception generating instructions, it is the address of the instruction that follows the exception generating instruction.

Note

If an exception generating instruction is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the exception generating instruction.

When an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the top 32 bits of the modified ELR_ELx are 0.

D1.10.2 Exception vectors

When the PE takes an exception to an Exception level that is using AArch64, execution is forced to an address that is the exception vector for the exception. The exception vector exists in a vector table at the Exception level the exception is taken to.

A vector table occupies a number of consecutive word-aligned addresses in memory, starting at the vector base address.

Each Exception level has an associated Vector Base Address Register (VBAR), that defines the exception base address for the table at that Exception level.

For exceptions taken to AArch64 state, the vector table provides the following information:

- Whether the exception is one of the following:
  - Synchronous exception.
  - SError.
  - IRQ.
  - FIQ.
- Information about the Exception level that the exception came from, combined with information about the stack pointer in use, and the state of the register file.
Table D1-7 shows this.

Table D1-7 Vector offsets from vector table base address

<table>
<thead>
<tr>
<th>Exception taken from</th>
<th>Offset for exception type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Synchronous</td>
</tr>
<tr>
<td>Current Exception level with SP_EL0.</td>
<td>0x000</td>
</tr>
<tr>
<td>Current Exception level with SP_ELx, x&gt;0.</td>
<td>0x200</td>
</tr>
<tr>
<td>Lower Exception level, where the implemented level immediately lower than the target level is using AArch64.(^a)</td>
<td>0x400</td>
</tr>
<tr>
<td>Lower Exception level, where the implemented level immediately lower than the target level is using AArch32.(^a)</td>
<td>0x600</td>
</tr>
</tbody>
</table>

\(^a\) For exceptions taken to EL3, if EL2 is implemented, the level immediately lower than the target level is EL2 if the exception was taken from Non-secure state, but EL1 if the exception was taken from Secure EL1 or EL0.

Reset is treated as a special vector for the highest implemented Exception level. This special vector uses an IMPLEMENTATION DEFINED address that is typically set either by a hardwired configuration of the PE or by configuration input signals. The RVBAR_ELx register contains this reset vector address, where \(x\) is the number of the highest implemented Exception level.

D1.10.3 Pseudocode description of exception entry to AArch64 state

The AArch64.TakeException() pseudocode function describes the behavior when the PE takes an exception to an Exception level that is using AArch64. The AArch64.ExceptionClass() function determines the EC (Exception class) and IL (Instruction length) values required to report the exception, and AArch64.ReportException() reports the exception.

The pseudocode functions AArch64.TakeException(), AArch64.ExceptionClass(), and AArch64.ReportException() are described in Chapter J1 ARMv8 Pseudocode.

D1.10.4 Exception classes and the ESR_ELx syndrome registers

If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the Exception level the exception is taken to. The information saved is determined at the time the exception is taken, and is not changed as a result of the explicit synchronization that takes place at the start of taking the exception. See Synchronization requirements for AArch64 System registers on page D10-2349. The following sections give more information:

- Use of the ESR_EL1, ESR_EL2, and ESR_EL3.
- The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1 on page D1-1881.

Use of the ESR_EL1, ESR_EL2, and ESR_EL3

An ESR_ELx holds the syndrome information for an exception that is taken to AArch64 state.

Note

This use of a syndrome is also the reporting model used for exceptions taken to Hyp mode when they are taken to EL2 using AArch32.

Figure D1-2 on page D1-1877 shows the general format of the ESR_ELx registers.
The ESR_ELx fields are:

- **EC, bits[31:26]** — The Exception class field, that indicates the cause of the exception.
- **IL, bit[25]** — The Instruction length bit, for synchronous exceptions, that indicates whether a trapped instruction was a 16-bit or a 32-bit instruction.
- **ISS, bits[24:0]** — The Instruction specific syndrome field. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

*ESR_ELx, Exception Syndrome Register (ELx)* on page D10-2436 describes the register in full, including:
- Listing the valid EC field values.
- Describing the ISS for each Exception class.
- Giving a full description of the use of the IL field.

Table D1-8 shows the encoding of the ESR_ELx.EC field, the Exception class field. For each EC value, the table references a subsection of the ESR_ELx register definition that describes the ISS format, with links to descriptions of possible causes of the exception, for example the configuration required to enable a trap.

- a. See also Reporting AArch32 synchronous exceptions taken to an Exception level using AArch64 on page D1-1881.
- b. Exceptions caused by configurable traps, enables, or disables.
- c. See Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1944.
- d. Only for MCR or MRRC accesses to the PMCCNTR_EL0 or PMCCNTR.
- e. Excludes exceptions that are generated because the value of HCR_EL2.TGE is 1, see The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1 on page D1-1881.
- f. Applies only to traps of accesses to MVFR0, MVFR1, MVFR2, or FPSID. Includes traps of VMRS accesses. Because the MVFRn registers are read-only and a VMRS access to the FPSID is ignored and not trapped, there are no MCR or VMRS accesses that can be trapped with this EC value.
- g. Only as a result of HCR_EL2.TGE.
- h. Only as a result of HCR_EL2.TSC.
- i. Only if SVE is implemented. Otherwise the EC value is reserved.
- j. Only if ARMv8.3-NV is implemented and HCR_EL2.NV is 1.
- k. Used for MMU faults generated by instruction accesses, and for synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
- l. Used for MMU faults generated by data accesses, Alignment faults other than SP alignment faults and PC alignment faults, and for synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
- m. Only as a result of HCR_EL2.TGE ==1 or MDCR_EL2.TDE ==1.
- n. Only if the BRK instruction is executed in EL3. This is the only debug exception that can be taken to EL3 when EL3 is using AArch64.

Reserved EC values

For EC values not shown in Table D1-8 on page D1-1877:

- Unused EC values in the range 0b0000000-0b101100 (0x00-0x2C) are reserved by ARM for future use for synchronous exceptions.
- Unused EC values in the range 0b101101-0b111111 (0x2D-0x3F) are reserved by ARM for future use, and might be used for synchronous or asynchronous exceptions.
The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1

When an exception is taken from EL0 to EL2 because the value of HCR_EL2.TGE is 1, the exception is reported in ESR_EL2. The EC value and corresponding ISS encoding used to report the exception in ESR_EL2 depend on how an exception of the same class would be reported in ESR_EL1 when the value of HCR_EL2.{TGE, RW} is \{0, 1\}:

- If the exception would have been reported in ESR_EL1 using the EC value 0x07 then it is reported in ESR_EL2 using the EC value 0x00 and corresponding ISS encoding.
- Otherwise, the exception is reported in ESR_EL2 using the EC value and ISS encoding that would have been used to report the exception ESR_EL1.

Reporting AArch32 synchronous exceptions taken to an Exception level using AArch64

Although possible exception causes are generally similar for AArch32 state and AArch64 state, AArch32 state has additional exception taxonomy that is not present in AArch64 state. The following sections described named AArch32 exceptions that can, in some contexts, be taken to an Exception level that is using AArch64:

- **Undefined Instruction exception** on page G1-4661.
- **Supervisor Call (SVC) exception** on page G1-4665.
- **Secure Monitor Call (SMC) exception** on page G1-4667.
- **Hypervisor Call (HVC) exception** on page G1-4668.
- **Prefetch Abort exception** on page G1-4669.
- **Data Abort exception** on page G1-4672.

When EL2 is using AArch64 and the value of HCR_EL2.TGE is 1, these exceptions are routed to EL2, and reported in ESR_EL2. Table D1-9 shows how they are reported.

<table>
<thead>
<tr>

</tbody>
</table>

a. The pseudocode in Operation for all encodings on page F5-3684 identifies when the execution of an SMC instruction in AArch32 state generates an exception that is taken to EL3 using AArch64.

D1.10.5 Summary of register updates on faults taken to an Exception level that is using AArch64

For all exceptions taken to an Exception level using AArch64 that are not listed in Validity of FAR_ELx on page D1-1882, the FAR_ELx for the Exception level the exception is taken to is UNKNOWN.

For all exceptions taken to EL2 using AArch64 that are not listed in Validity of HPFAR_EL2 on page D1-1882, the HPFAR_EL2 is UNKNOWN.

The following sections give more information:

- Validity of FAR_ELx on page D1-1882.
- Validity of HPFAR_EL2 on page D1-1882.
Validity of FAR_ELx

The faulting virtual address is saved in FAR_ELx for the Exception level the exception is taken to if an exception is one of:

- An Instruction Abort exception.
- A Data Abort exception.
- A PC alignment fault exception.
- A Watchpoint exception.

The architecture permits that the FAR_ELx is UNKNOWN for synchronous External aborts other than synchronous External aborts on translation table walks. In this case, the ISS.FnV bit returned in ESR_ELx indicates whether FAR_ELx is valid.

If an exception is taken from an Exception level using AArch32 into an Exception level using AArch64, and that exception writes the FAR_ELx at the Exception level the exception is taken to, the most significant 32 bits of FAR_ELx are all zero, unless both of the following apply, in which case the most significant 32 bits of FAR_ELx are 0x00000001:

- The faulting address was generated by a load or store that sequentially incremented from address 0xFFFFFFFF.
  Such a load or store instruction is CONSTRAINED UNPREDICTABLE, see Out of range VA on page K1-6399.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

The FAR_ELx for an Exception level is made UNKNOWN as a result of an exception return from that Exception level.

Validity of HPFAR_EL2

The faulting IPA is saved in HPFAR_EL2 if the exception is an Instruction Abort or Data Abort taken to EL2 and the fault is one of:

- A Translation or Access Flag fault on a stage 2 translation.
- A stage 2 Address Size fault.
- A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.

HPFAR_EL2 is made UNKNOWN as a result of an exception return from EL2.
D1.11 Exception return

In the ARMv8-A architecture, an exception return is always to the same Exception level or a lower Exception level. An exception return is used for:

- A return to a previously executing thread.
- Entry to a new execution thread. For example:
  - The initialization of a hypervisor by a Secure monitor.
  - The initialization of an operating system by a hypervisor.
  - Application entry from an operating system or hypervisor.

An exception return requires the simultaneous restoration of the PC and PSTATE to values that are consistent with the desired state of execution on returning from the exception.

In AArch64 state, an ERET instruction causes an exception return, see ERET on page C6-638.

If ARMv8.2-IESB is implemented, when the SCTLR_ELx.IESB bit at the Exception level the exception is returning from is 1, the PE inserts an error synchronization event before the ERET instruction. See ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

On executing an ERET instruction at ELx:

- The PC is restored with the value held in ELR_ELx.
- PSTATE is restored by using the contents of SPSR_ELx.

ELR_ELx and SPSR_ELx are the ELR_ELx and SPSR_ELx at the Exception level the exception is returning from. The exception return makes this ELR_ELx and SPSR_ELx UNKNOWN.

See Address tagging in AArch64 state on page D4-2084 for details of how tagged addresses are handled in an Exception return from an Exception level using AArch64 to an Exception level using AArch64.

Note

When returning from an Exception level using AArch64 to an Exception level using AArch32, the top 32 bits of the ELR_ELx are ignored.

An ERET instruction also:

- Sets the Event Register for the PE executing the ERET instruction. See Mechanisms for entering a low-power state on page D1-1954.
- Resets the local Exclusives monitor for the PE executing the ERET instruction. This removes the risk of errors that might be caused when a path to an exception return fails to include a CLREX instruction.

Note

This behavior prevents self-hosted debug from software stepping through a Load-Exclusive/Store-Exclusive pair. However, when self-hosted debug is using software step, it is highly probable that the Exclusives monitor state would be lost anyway, for other reasons. Stepping code that uses Exclusives monitors on page D2-2044 describes this.

It is IMPLEMENTATION DEFINED whether the resetting of the local Exclusives monitor also resets the global Exclusives monitor.

The ERET instruction is UNDEFINED in EL0.

When returning from an Exception level using AArch64 to an Exception level using AArch32, the AArch32 context is restored. The ARMv8-A architecture defines the relationship between AArch64 state and AArch32 state, for:

- General-purpose registers.
- Special-purpose registers.
- System registers.

In an implementation that includes EL3, the Security state can only change on returning from an exception if the return is from EL3 to a lower Exception level.
The following sections give more information:

- Exception return and PC alignment.
- Illegal return events from AArch64 state.
- Legal returns that set PSTATE.I to 1 on page D1-1886.
- The Illegal Execution state exception on page D1-1886.
- Pseudocode description of exception return on page D1-1886.

D1.11.1 Exception return and PC alignment

When SPSR_ELx.M[4] == 0, indicating an Exception return to AArch64 state, the value of ELR_ELx is transferred to the PC. If this value is misaligned, subsequent execution results in a PC alignment fault exception.

When SPSR_ELx.M[4] == 1, indicating an Exception return to AArch32 state, the value of ELR_ELx is transferred to the PC except that, for a legal exception return:

- If SPSR_ELx.T is 0, ELR_ELx[1:0] are treated as being 0 for restoring the PC.
- If SPSR_ELx.T is 1, ELR_ELx[0] is treated as being 0 for restoring the PC.

This means that a PC alignment fault exception cannot occur following a legal exception return from AArch64 state to AArch32 state. However, where the Exception return with SPSR_ELx.M[4] == 1 is an illegal exception return then it is IMPLEMENTATION DEFINED whether a misaligned value in ELR_ELx is aligned when it is restored to the PC.

Note

In an implementation that forces the alignment of the PC value restored from SPSR_ELx on an illegal exception return with SPSR_ELx.M[4] == 1, if SPSR_ELx.T == 1 the restored PC value might give rise to a PC alignment fault exception, because the PE remains in AArch64 state and only ELR_ELx[0] is treated as being 0 for restoring the PC.

For more information about the illegal exception return cases see Illegal return events from AArch64 state.

D1.11.2 Illegal return events from AArch64 state

In this section:

**Return**

- In AArch64 state, refers to any of:
  - Execution of an ERET instruction.
  - Execution of a DRPS instruction in Debug state.
  - Exit from Debug state.

**Saved process state value**

- In AArch64 state, refers to any of:
  - The value held in the SPSR_ELx for an ERET instruction.
  - The value held in the SPSR_ELx for a DRPS instruction executed in Debug state.
  - The value held in the DSPSR_EL0 for a Debug state exit.

**Link address**

- In AArch64 state, refers to any of:
  - The address held in ELR_ELx for an ERET instruction.
  - The address held in DLR_EL0 for a Debug state exit.

**Configured from reset**

- Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling returns to a mode or state that is illegal. In AArch64 state, this can occur as the result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the Exception level being returned to is not implemented. For example a return to EL2 when EL2 is not implemented.
• A return to EL2 when EL3 is implemented and the value of the SCR_EL3.NS bit is 0.

• A return to Non-secure EL1 when EL2 is implemented and the value of the HCR_EL2.TGE bit is 1.

• A return where the value of the saved process state M[4] bit is 0, indicating a return to AArch64 state, and one of the following is true:
  — The M[3:0] bits are \texttt{0b0001}.
  — The Exception level being returned to is using AArch32 state, as programmed by the SCR_EL3.RW or HCR_EL2.RW bits, or as configured from reset.

• A return where the value of the saved process state M[4] bit is 1, indicating a return to AArch32 state, and one of the following is true:
  — The M field value is not a valid AArch32 state PE mode. Table D1-4 on page D1-1863 shows the valid M[3:0] values for AArch32 state PE modes. This includes the case where M[3:0] is \texttt{0b0000}, indicating User mode, and EL0 does not support AArch32 state.
  — The Exception level being returned to is using AArch64 state as determined by the SCR_EL3.RW or HCR_EL2.RW field or the configuration from reset. This includes the case where the Exception level being returned to does not support AArch32 state.

**Note**

This means that, in an implementation that supports only AArch64 state, any attempt to return to AArch32 state is an illegal exception return.

• A Debug state exit from EL0 using AArch64 state, to EL0 using AArch32 state.

In these cases:

• \texttt{PSTATE.IL} is set to 1, to indicate an illegal return.

• \texttt{PSTATE.{EL, nRW, SP}} are unchanged. This means the Exception level, Execution state, and stack pointer selection do not change as a result of the return.

• The following \texttt{PSTATE} bits are restored from the saved process state value:
  — The D, A, I, F exception mask bits.

• If the illegal return is an illegal exception return, the \texttt{PSTATE.SS} bit is handled as normal for a return. That is, the SS bit is handled in the same way as an exception return that is not an illegal exception return. See \textit{Software Step exceptions} on page D2-2032.

  In all these cases the \texttt{PSTATE.SS} bit is handled as it would be for a normal return, as described in \textit{Entering the active-not-pending state} on page D2-2034 and \textit{Exiting Debug state} on page H2-5733. DRPS never sets the SS bit. This is indicated in \textit{Entering the active-not-pending state} on page D2-2034.

• If the illegal return is not a DRPS instruction executed in Debug state, the PC is restored from the link address. However, if the value of the M[4] bit of the saved process state is 1, indicating a return to AArch32 state, then:
  — Bits[31:2] of the PC are restored from the link address.
  — Bits[63:32, 1:0] of the PC are \texttt{UNKNOWN}.

When the value of the \texttt{PSTATE.IL} bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See \textit{The Illegal Execution state exception} on page D1-1886.

All aspects of the illegal return, other than the effects described in this section, occur as they do for a legal return.
D1.11.3 Legal returns that set PSTATE.IL to 1

In this section, return, saved process state value, and link address have the same meaning as defined in Illegal return events from AArch64 state on page D1-1884.

If the value of the IL bit in the saved process state is 1, then it is copied to PSTATE by a return, meaning that PSTATE.IL is set to 1. In this case, if the return is not an illegal return, and targets AArch32 state, then the PSTATE.{IT, T} bits are either:
- Set to 0.
- Copied from the saved process state value.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The PSTATE.{IT, T} bits are only valid in AArch32 state; see Process state, PSTATE on page G1-4614.

When the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See The Illegal Execution state exception.

D1.11.4 The Illegal Execution state exception

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. In AArch64 state, the PSTATE.IL bit can be set to 1 by any of:
- An illegal return, as described in Illegal return events from AArch64 state on page D1-1884.
- A legal return that sets PSTATE.IL to 1, as described in Legal returns that set PSTATE.IL to 1.

An Illegal Execution state exception sets ESR_ELx.EC for the target Exception level to the value of 0x0E.

On taking any exception to an Exception level that is using AArch64 state:
1. The value of the PSTATE.IL bit is copied into the SPSR_ELx.IL bit for the Exception level to which the exception is taken.
2. The PSTATE.IL bit is cleared to 0.

Note
This means that it is not possible for software to observe the value of PSTATE.IL.

For the priority of this exception class, see Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895.

D1.11.5 Pseudocode description of exception return

The AArch64.ExceptionReturn() pseudocode function transfers the return address to the PC, and restores PSTATE to its saved value by calling SetPSTATEFromPSR().

The IllegalExceptionReturn() function checks for an Illegal Execution state exception.
D1.12 The Exception level hierarchy

The System registers provide controls that control PE behavior through the Exception level hierarchy.

If EL3 and EL2 are implemented, System registers at EL3 and EL2 provide controls that control the Execution state of lower Exception levels.

Table D1-10 shows the principal System registers.

### Table D1-10 Principal System registers

<table>
<thead>
<tr>
<th>EL3</th>
<th>EL2</th>
<th>EL1</th>
<th>Notes</th>

<td>-</td>
<td>Used only if at least one of EL1 and EL0 is using AArch32.</td>
</tr>
</tbody>
</table>

The prioritization of exceptions generated as a result of controls in these registers is described in Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895.

The following sections describe the Exception level hierarchy:

- The hierarchy of configuration and routing control.
- Control of SIMD, floating-point and trace functionality on page D1-1893.
- Control of IMPLEMENTATION DEFINED features on page D1-1893.
- Routing exceptions from Non-secure EL0 to EL2 on page D1-1895.

D1.12.1 The hierarchy of configuration and routing control

The following subsections give a summary of the controls available at each Exception level for controlling execution at that Exception level and all lower Exception levels:

- Controls provided at EL3.
- Controls provided at EL2 on page D1-1889.
- Controls provided at EL1 on page D1-1891.

For information on how the controls summarized in these subsections affect PE behavior, see the definitions of the control bits in the register descriptions.

**Controls provided at EL3**

See:

- Controls provided by the SCR_EL3.
- Controls provided by the SCTLR_EL3 on page D1-1888.
- Controls provided by the MDCR_EL3 on page D1-1888.

**Controls provided by the SCR_EL3**

**SCR_EL3.NS** Determines the Security state of execution at EL1 and EL0.

**SCR_EL3.RW** Determines the Execution state of the next-lower Exception level.

**SCR_EL3.{EA, FIQ, IRQ}**

Route:

- **EA** Physical SError interrupts and synchronous External aborts to EL3.
- **FIQ** Physical FIQ interrupts to EL3.
- **IRQ** Physical IRQ interrupts to EL3.

**SCR_EL3.SMD** Disables the Secure Monitor Call exception.
SCR_EL3.HCE  Enables the Hypervisor Call exception.
SCR_EL3.ST   Enables Secure EL1 access to the Secure timer.
SCR_EL3.SIF  Secure Instruction Fetch. When in Secure state, disables instruction fetches from Non-secure memory.
SCR_EL3.TWI  Trap Wait-For-Interrupt.
SCR_EL3.TWE  Trap Wait-For-Event.
SCR_EL3.TERR Trap error record accesses. This field is part of the RAS Extension.

Controls provided by the SCTLR_EL3

SCTLR_EL3.{A, SA} Enable alignment checking:
 A  On data accesses from EL3.
 SA  On the SP, when executing at EL3.

SCTLR_EL3.{M, C, I, WXN}
Memory system control bits:
 M  Enables EL3 stage 1 address translation.
 C  When set to 0, makes data accesses to Normal memory from EL3, and Normal memory accesses to the EL3 translation tables, Non-cacheable.
 I  When set to 0, makes instruction accesses to Normal memory from EL3 Non-cacheable.
 WXN  For accesses from EL3, enables treating all writable memory regions as XN, execute-never.

SCTLR_EL3.EE  Defines the endianness of data accesses from EL3, including stage 1 translation table walks at EL3.

——— Note ————
Instruction fetches are always little-endian.

Controls provided by the MDCR_EL3

MDCR_EL3.{EPMAD, EDAD}
Enable external debugger accesses to:
EPMAD  Performance Monitors registers.
EDAD  Breakpoint and Watchpoint registers.

MDCR_EL3.{SPME, SDD, SPD32}
Secure debug controls:
SPME  Secure Performance Monitors enable. Enables event counting in Secure state.
SDD  Disables all debug exceptions taken from Secure state, if the debug target Exception level, ELD, is using AArch64.
SPD32  Enables debug exceptions from Secure EL1 using AArch32.

MDCR_EL3.{TDOSA, TDA, TPM}
These are trap controls, that control traps to EL3 of EL2, EL1, and EL0 accesses to the following:
TDOSA  The OS-related debug registers.
TDA  Those debug registers not included in the MDCR_EL3.TDOSA trap.
TPM  The Performance Monitors registers.
For EL1 and EL0, these traps apply to accesses from both Security states.
Controls provided at EL2

EL2 is implemented only in Non-secure state, and its controls apply only to execution in Non-secure EL2, Non-secure EL1, and Non-secure EL0. See:
- Controls provided by SCTLR_EL2.
- Controls provided by HCR_EL2.
- Controls provided by the HSTR_EL2 on page D1-1891.
- Controls provided by the MDCR_EL2 on page D1-1891.

Controls provided by SCTLR_EL2

SCTLR_EL2.{A, SA} Enable alignment checking:
- A On data accesses from EL2.
- SA On the SP, when executing at EL2.

SCTLR_EL2.{M, C, I, WXN}

Memory system control bits:
- M Enables EL2 stage 1 address translation.
- C When set to 0, makes data accesses to Normal memory from EL2, and Normal memory accesses to the EL2 translation tables, Non-cacheable.
- I When set to 0, makes instruction accesses to Normal memory from EL2 Non-cacheable.
- WXN For accesses from EL2, enables treating all writable memory regions as XN, execute-never.

SCTLR_EL2.EE Defines the endianness of data accesses from EL2, including stage 1 translation table walks at EL2. Also defines the endianness of stage 2 translation table walks at Non-secure EL1 and EL0.

--- Note ---
Instruction fetches are always little-endian.

Controls provided by HCR_EL2

HCR_EL2.RW Determines the Execution state of the next-lower Exception level.

HCR_EL2.{AMO, IMO, FMO}

Route physical interrupts to EL2, and if the value of HCR_EL2.TGE is 0, enable virtual interrupts:
- AMO Route physical SError interrupts to EL2 and enable virtual SError interrupts
- IMO Route physical IRQ interrupts to EL2 and enable virtual IRQ interrupts.
- FMO Route physical FIQ interrupts to EL2 and enable virtual FIQ interrupts.

--- Note ---
- If a physical interrupt is routed to both EL3 and EL2, routing to EL3 takes precedence over routing to EL2.
- When the value of HCR_EL2.TGE is 0, the virtual interrupt enables apply regardless of whether the corresponding physical interrupt is routed to EL2 or to EL3.
- In ARMv8.0, when the value of HCR_EL2.TGE is 1 the virtual interrupts are disabled.
- From ARMv8.1, when the value of HCR_EL2.TGE is 1:
  - If ARMv8.1-VHE is not implemented, or if HCR_EL2.E2H is 0, these fields behave as 1 for all purposes other than a direct read of the value of the fields.
— If ARMv8.1-VHE is implemented and HCR_EL2.E2H is 1, these fields behave as 0 for all purposes other than a direct read of the value of the fields.

**HCR_EL2.[VSE, VI, VF]**

Cause a virtual interrupt to be pending:

- **VSE** Virtual SError interrupt.
- **VI** Virtual IRQ interrupt.
- **VF** Virtual FIQ interrupt.

**HCR_EL2.VM**

Enable bit for Non-secure EL1&0 stage 2 address translations.

**HCR_EL2.[SWIO, PTW, FB, BSU, DC, CD, ID]**

Controls for memory system behavior for accesses made from Non-secure EL1 and EL0:

- **SWIO** Set/Way Invalidate Override.
- **PTW** Protect Table Walk.
- **FB** Force broadcast of TLB and instruction cache maintenance instructions.
- **BSU** Barrier Shareability Upgrade.
- **DC** Default Cacheability control for the EL1&0 translation regime.
- **CD** For the Non-secure EL1&0 translation regime, when set to 1, forces stage 2 translation table walks to Normal memory, and stage 2 translations for data accesses to Normal memory, to be Non-cacheable.
- **ID** For the Non-secure EL1&0 translation regime, when set to 1, forces stage 2 translations for instruction accesses to Normal memory be Non-cacheable.

**HCR_EL2.HCD**

Hypervisor Call Disable.

— **Note** —

If an implementation includes EL3, this bit is RES0.

**HCR_EL2.[TRVM, TDZ, TVM, TTLB, TPU, TPC, TSW, TACR, TIDCP, TSC, TID1, TID2, TID3, TWE, TWI, TERR]**

Trap operations performed at Non-secure EL1 or EL0 to EL2, as follows:

- **TRVM** Trap Read of Virtual Memory controls.
- **TDZ** Trap Data Cache Zero.
- **TVM** Trap Virtual Memory controls.
- **TTLB** Trap TLB maintenance instructions.
- **TPU** Trap cache maintenance to the Point of Unification instructions.
- **TPC** Trap data cache maintenance to the Point of Coherency instructions.
- **TSW** Trap data cache maintenance by Set/Way instructions.
- **TACR** Trap Auxiliary Control Register accesses.
- **TIDCP** Trap Implementation-Dependent functionality.
- **TSC** Trap Secure Monitor Call.
- **TID0** Trap ID Group 0 register accesses.
- **TID1** Trap ID Group 1 register accesses.
- **TID2** Trap ID Group 2 register accesses.
- **TID3** Trap ID Group 3 register accesses.
- **TWI** Trap Wait-For-Interrupt.
- **TWE** Trap Wait-For-Event.
- **TERR** Trap error record accesses. This field is part of the RAS Extension.
Note

There are no AArch64 System registers in ID Group 0, therefore the TID0 trap is only relevant when Non-secure EL1 is using AArch32.

HCR_EL2.TGE

Trap General Exceptions.

HCR_EL2.TEA

Route synchronous External abort exceptions to EL2. This field is part of the RAS Extension.

Controls provided by the HSTR_EL2

When EL2 is using AArch64 and at least one of Non-secure EL1 or EL0 is using AArch32, HSTR_EL2 provides the following trap of Non-secure AArch32 operation to EL2:

HSTR_EL2.Tn, for values of n in the set {0-3, 5-13, 15}

Trap accesses to System registers in the AArch32 (coproc==0b1111) encoding space, by the value of n, where n is:

- The numeric value of the CRn argument used when accessing the register using an MCR or MRC instruction.
- The numeric value of the CRn argument used when accessing the register using an MCRR or MRRC instruction.

Controls provided by the MDCR_EL2

MDCR_EL2.{TDRA, TDOSA, TDA}

Trap controls, that control traps to EL2 of Non-secure EL1 and EL0 System register accesses to the following:

TDRA The Debug ROM registers.
TDOSA The OS-related debug registers.
TDA Those debug registers not included in either of the MDCR_EL2.TDRA or MDCR_EL2.TDOSA traps.

MDCR_EL2.TDE

Routes all debug exceptions taken from Non-secure EL1 and EL0 to EL2.

MDCR_EL2.{TPM, TPMCR}

These are trap controls, that control traps to EL2 of Non-secure EL1 and EL0 accesses to the following registers:

TPM All Performance Monitors registers.
TPMCR The Performance Monitors Control Registers.

MDCR_EL2.HPMN

Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 and EL0.

Controls provided at EL1

See:

- Controls provided by the SCTLR_EL1.
- Controls provided by the MDSCR_EL1 on page D1-1892.

Controls provided by the SCTLR_EL1

SCTLR_EL1.{A, SA}

Enable alignment checking:

- A On data accesses from EL1 and EL0.
- SA On the SP, when executing at EL1.

SCTLR_EL1.SA0

Enable alignment checking on the SP when executing at EL0.
**SCTLR_EL1.{M, C, I, WXN]**

Memory system control bits:

- **M** Enables EL1&0 stage 1 address translation.
- **C** When set to 0, makes data accesses to Normal memory from EL0 and EL1, and Normal memory accesses to the EL1&0 stage 1 translation tables, Non-cacheable.
- **I** When set to 0, makes instruction accesses to Normal memory from EL1 and EL0 Non-cacheable.
- **WXN** For accesses from EL1 and EL0, enables treating all writable memory regions as XN, execute-never.

**SCTLR_EL1.EE** Defines the endianness of data accesses from EL1, including stage 1 translation table walks at EL1 and EL0.

---
**Note**

Instruction fetches are always little-endian.

---

**SCTLR_EL1.E0E** EL0 Endianness. Defines the endianness used for explicit data accesses made from EL0.

**SCTLR_EL1.{UCI, UCT, DZE, nTWI, nTWE}**

Trap enables:

- **UCI** Unprivileged Cache maintenance Instruction enable.
- **UCT** Unprivileged Cache Type access enable.
- **DZE** Data cache Zero Enable.
- **nTWI** Not Trap Wait-For-Interrupt.
- **nTWE** Not Trap Wait-For-Event.

**SCTLR_EL1.UMA** Unprivileged Mask Access.

**SCTLR_EL1.{SED, ITD, CP15BEN}**

These bits control the use, at EL0, of AArch32 functionality that is deprecated, or OPTIONAL and deprecated:

- **SED** Disables use of the SETEND instruction.
- **ITD** If supported, disables some uses of the IT instruction. The register field description identifies the uses that are disabled.
- **CP15BEN** If supported, enables use of the CP15DMB, CP15DSB, and CP15ISB memory barrier instructions.

The deprecated uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB instructions, are deprecated for performance reasons. Implementation of the ITD and CP15BEN controls is optional, and if a control is not implemented then the associated AArch32 functionality cannot be disabled.

**Controls provided by the MDSCR_EL1**

**MDSCR_EL1.{MDE, SS}**

Enable controls for the debug exceptions:

- **MDE** Enables Breakpoint exceptions, Watchpoint exceptions, and Vector Catch exceptions.
- **SS** Enables Software Step exceptions.

There is no enable control for Breakpoint Instruction exceptions. Breakpoint Instruction exceptions are always enabled.

**MDSCR_EL1.KDE** Enables debug exceptions from EL_D when EL_D is using AArch64.
MDSCR_EL1.TDCC Enables a trap to EL1 of EL0 accesses to the Debug Communications Channel registers.

**D1.12.2 Control of SIMD, floating-point and trace functionality**

In addition to the controls described in *The hierarchy of configuration and routing control on page D1-1887*, the following registers provide a hierarchy of control of access to SIMD and floating-point functionality, and to trace functionality that is accessible using the System registers:

- **CPTR_EL3** Traps operation at lower Exception levels to EL3, if the operation is not trapped to EL2 by CPTR_EL2 and is not trapped to EL1 by CPACR_EL1.

- **CPTR_EL2** Traps operation in Non-secure EL1 or EL0 to EL2, if the operation is not trapped to EL1 by CPACR_EL1. CPTR_EL2.{TTA, TFP} also trap operation in EL2.

  The trap bits in the CPTR_EL3 and CPTR_EL2 are as follows:

  - **TCPAC** Traps accesses to the registers that control access to SIMD, floating-point, and trace functionality.
  - **TTA** Traps any System register access to trace functionality, unless that access is otherwise trapped to a lower Exception level.
  - **TFP** Traps any execution of an instruction that uses the SIMD and floating-point register bank, unless that access is otherwise trapped to a lower Exception level.

- **CPACR_EL1** Traps operation from EL1 or EL0 to EL1. Traps set in the CPACR_EL1 take precedence over any traps set in the CPTR_EL2 or CPTR_EL3. The trap fields are as follows:

  - **TTA** Traps to EL1 any System register access from EL0 or EL1 to trace functionality.
  - **FPEN** Traps to EL1 execution of instructions that uses the SIMD and floating-point register bank.

**D1.12.3 Control of IMPLEMENTATION DEFINED features**

*The hierarchy of configuration and routing control on page D1-1887* and *Control of SIMD, floating-point and trace functionality* describe the controls of the trapping of architecturally-defined functionality. However, the architecture also defines registers that can be used to provide IMPLEMENTATION DEFINED traps of IMPLEMENTATION DEFINED functionality to the different Exception levels. *Table D1-11* shows these control registers, for AArch64 state controls.

D1.13 Synchronous exception types, routing and priorities

Synchronous exceptions are:

- Any exception generated by attempting to execute an instruction that is UNDEFINED, including:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instructions when they are disabled.
  - Attempts to execute instruction bit patterns that have not been allocated.

- Illegal Execution state exceptions. These are caused by attempts to execute an instruction when the value of PSTATE.IL is 1, see Illegal return events from AArch64 state on page D1-1884.

- Exceptions caused by the use of a misaligned SP.

- Exceptions caused by attempting to execute an instruction with a misaligned PC.

- Exceptions caused by the exception-generating instructions SVC, HVC, or SMC.

- Traps on attempts to execute instructions that the System registers define as instructions that are trapped to a higher Exception level. See Configurable instruction enables and disables, and trap controls on page D1-1910.

- Instruction Aborts generated by the memory address translation system that are associated with attempts to execute instructions from areas of memory that generate faults.

- Data Aborts generated by the memory address translation system that are associated with attempts to read or write memory that generate faults.

- Data Aborts caused by a misaligned address.

- All of the debug exceptions:
  - Breakpoint Instruction exceptions.
  - Breakpoint exceptions.
  - Watchpoint exceptions.
  - Vector Catch exceptions.
  - Software Step exceptions.

- In an implementation that supports the trapping of floating-point exceptions, exceptions caused by trapped IEEE floating-point exceptions, see Floating-point exceptions and exception traps on page D1-1899.

- In some implementations, External aborts. External aborts are failed memory accesses, and include accesses to those parts of the memory system that occur during the address translation. The ARMv8 architecture permits, but does not require, implementations to treat such exceptions synchronously. See External aborts on page D3-2074.

This remainder of this section contains the following:

- Routing exceptions from Non-secure EL0 to EL2 on page D1-1895.
- Routing debug exceptions in Non-secure state to EL2 on page D1-1895.
- Routing synchronous External aborts on page D1-1895
- Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895.
- Effect of Data Aborts on page D1-1899.
- Floating-point exceptions and exception traps on page D1-1899.
D1.13.1 Routing exceptions from Non-secure EL0 to EL2

When the value of HCR_EL2.TGE is 1, any exception taken from Non-secure EL0 that would otherwise be taken to Non-secure EL1 is, instead, routed to EL2. This means that an application can execute at Non-secure EL0 without using any functionality at Non-secure EL1.

--- Note ---

- When EL2 is using AArch64, the HCR_EL2.TGE control applies regardless of whether Non-secure EL0 is using AArch32 or AArch64.
- Implementations typically use the following Exception level and software hierarchy in Non-secure state:
  
  - EL2: Hypervisor.
  - EL1: Operating system.
  - EL0: Application.

In such an implementation, setting HCR_EL2.TGE to 1 means that an application can run at Non-secure EL0 under the direct control of a hypervisor executing at EL2, with no operating system involvement.

---

D1.13.2 Routing debug exceptions in Non-secure state to EL2

When the value of MDCR_EL2.TDE is 1, debug exceptions taken from Non-secure state are routed to EL2. For more information see Routing debug exceptions on page D2-1985.

When the value of MDCR_EL2.TDE is 1, each of the MDCR_EL2.{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than direct reads of the MDCR_EL2.

D1.13.3 Routing synchronous External aborts

When the value of SCR_EL3.EA is 1, synchronous external aborts are taken to EL3.

When the RAS Extension is implemented, and the value of HCR_EL2.TEA is 1, synchronous external aborts from Non-secure EL0 and EL1 that are not routed to EL3 are routed to EL2.

D1.13.4 Synchronous exception prioritization for exceptions taken to AArch64

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. For exceptions taken to an Exception level that is using AArch64, these are prioritized as follows, where 1 is the highest priority.

--- Note ---

The priority numbering in this list only shows the relative priorities of exceptions taken to an Exception level that is using AArch64. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4626.

2. PC alignment fault exceptions. See PC alignment checking on page D1-1868.
3. Instruction Abort exceptions. See AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2198.
4. Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
   - Breakpoint exceptions on page D2-1995.
   - Vector Catch exceptions on page D2-2031.

Vector Catch exceptions are only taken from AArch32 state.
5. Illegal Execution state exceptions. See **Illegal return events from AArch64 state on page D1-1884**.

6. Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
   - HSTR_EL2.Tn.
   - HCR_EL2.TIDCP.

   **Note**
   These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are HSTR.Tn and HCR.TIDCP.

7. Exceptions that occur as a result of attempting to execute an instruction that is **UNDEFINED** for one or more of the following reasons:
   - Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
   - Attempting to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.

   **Note**
   This includes the **UNDEFINED** cases that are trapped to EL2 when ARMv8.3-NV is implemented and the value of HCR_EL2.NV is 1. That is, an HCR_EL2.NV value of 1 effectively reroutes the exception that is generated by the access being **UNDEFINED**.

   - Debug state execution of an instruction encoding that is unallocated in Debug state.
   - Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
   - Execution of an HVC instruction, when HVC instructions are disabled by SCR_EL3.HCE or HCR_EL2.HCD.
   - Execution of an MSR or MRS instruction to SP_EL0 when the value of SPSel is 0.
   - Execution of an HLT instruction when HLT instructions are disabled by EDSCR.HDE.
   - In Debug state:
     - Execution of a DCPS1 instruction in Non-secure EL0 when HCR_EL2.TGE is 1.
     - Execution of a DCPS2 instruction in EL1 or EL0 when SCR_EL3.NS is 0 or when EL2 is not implemented.
     - Execution of a DCPS3 instruction when EDSCR.SDD is 1 or when EL3 is not implemented.
     - When the value of EDSCR.SDD is 1, execution in EL2, EL1, or EL0 of an instruction that is configured by EL3 control registers to trap to EL3. It is IMPLEMENTATION DEFINED whether this type of exception is prioritized at this level or has the priority of the original trap exception.
   - When executing in AArch32 state, execution of an instruction that is **UNDEFINED** as a result of any of:
     - Being in an IT block when SCTLR_EL1.ITD is 1.
     - Executing a SETNØ instruction executed SCTLR_EL1.SED.
     - Executing a CP15DMB, CP15DSB, or CP15ISB barrier instruction when SCTLR_EL1.CP15BEN is 0.

   **Note**
   These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are SCTLR.[ITD, SED, CP15BEN], with additional controls HSCTLR.[ITD, SED, CP15BEN].
See Disabling or enabling EL0 use of AArch32 deprecated functionality on page D1-1915

- When executing in AArch32 state, execution of an instruction that is UNDEFINED because at least one of FPSCR.\{Stride, Len\} is nonzero, when programming these bits to nonzero values is supported. See Floating-point exceptions and exception traps on page G1-4700.

Note — This case applies only when EL0 is using AArch32 and EL1 is using AArch64. The exception generated by the attempted execution at EL0 of the UNDEFINED instruction is taken to EL1 using AArch64.

- When EL1 is using AArch32, the corresponding controls are FPSCR.\{Stride, Len\}, and any exception generated by the attempted execution at EL0 or EL1 of an instruction that is UNDEFINED because of a nonzero \{Stride, Len\} value is taken to EL1 using AArch32.

8. Exceptions taken to EL1, or taken to EL2 because the value of HCR_EL2.TGE is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 1-7.

Note — When EL2 is using AArch32, the equivalent control for routing exceptions to EL2 is HCR.TGE.

9. Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
   - HSTR_EL2.Tn.
   - HCR_EL2.TIDCP.

Note — These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are HSTR.Tn and HCR.TIDCP.

10. Exceptions taken to EL2 because of configuration settings in CPTR_EL2.

Note — These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are in HCPTR.

11. Exceptions taken to EL2 because of one of the following configuration settings:
   - Any setting in HCR_EL2 other than the \{TIDCP, NV\} fields.
   - Any setting in CNTHCTL_EL2.
   - Any setting in MDCR_EL2.

Note — These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, equivalent controls are:
   - Settings in HCR, other than the TIDCP bit.
     For exceptions taken to AArch32 state there is no control equivalent to HCR_EL2.NV.
   - Any setting in CNTHCTL or HDCR.

12. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 1-11.

13. Exceptions caused by the SMC instruction being UNDEFINED because the value of SCR_EL3.SMD is 1.

14. Exceptions caused by the execution of an Exception generating instruction:
   - For exceptions taken from AArch64 state, Branches, Exception generating, and System instructions on page C3-162 defines these instructions.
• When executing in AArch32 state, the exception-generating instructions are SVC, HVC, SMC, and BKPT.

15. Exceptions taken to EL3 because of configuration settings in the CPTR_EL3.

  Note
  When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

16. Exceptions taken to EL3 from Secure EL1 using AArch32, because of execution of the instructions listed in `Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1944`.

17. Exceptions taken to EL3 from EL0, EL1, or EL2 because of configuration settings in the MDCR_EL3.

  Note
  When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

18. Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 1-17.

  Note
  When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

19. Trapped floating-point exceptions, if supported. See `Floating-point exceptions and exception traps on page D1-1899`.

20. SP alignment faults. See `SP alignment checking on page D1-1868`.

21. Data Abort exceptions other than a Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by item 23. See `AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2198`. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as item 23.

23. Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk, see `External aborts on page D3-2074`. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as item 21.

For items 21-23, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

  Note
  Exceptions generated by a translation table walk are reported and prioritized as either an Instruction Abort exception, priority 3 in this list, or a Data Abort exception, priority 21 in this list. See also `AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2198`. 
D1.13.5 Effect of Data Aborts

If an instruction that stores to memory generates a Data Abort, the value of each memory location that instruction stores to is either:

• Unchanged, if one of the following applies:
  — An Alignment fault is generated.
  — An MMU fault is generated.
  — A Watchpoint exception is generated.
  — An External abort is generated, if that External abort is taken synchronously.

  Note
  If an External abort is taken asynchronously, using the SError interrupt, it is outside the scope of the architecture to define the effect of the store on the memory location, because it depends on the system-specific nature of the External abort. However, in general, ARM recommends that such memory locations are not updated.

• UNKNOWN for any location for which no exception and no debug event is generated.

For External aborts and Watchpoint exceptions, the size of a memory location is defined as being the size for which a memory access is single-copy atomic.

  Note
  For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page B2-89.

An External abort might signal a data corruption to the PE. For example a memory location might have been corrupted. The error that caused the External abort might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

For Data Aborts from load or store instructions executed in AArch64 state, if the:

Data Abort is taken synchronously

• If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.

• If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.

• If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

Data Abort is taken asynchronously, using the SError interrupt

If the instruction was a load, the destination registers of the load take an UNKNOWN value if the SError interrupt is taken at a point in the instruction stream after the load.

D1.13.6 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a floating-point exception.

  Note
  In AArch64 state, a floating-point instruction performs only a single floating-point operation. However, an Advanced SIMD instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an operation, rather than on an instruction.
The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the different floating-point exceptions.
- For an implementation that does not provide this capability, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits are RAZ/WI.

--- Note ---

- An Input Denormal floating-point exception is generated when a single-precision or double-precision floating-point value is flushed-to-zero because the value of FPCR.FZ is 1. However, no Input Denormal exception is generated when a half-precision floating-point value is flushed-to-zero because the value of FPCR.FZ16 is 1.
- The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken:

- From EL0 are taken to EL1, unless they are taken from Non-secure state when the value of HCR_EL2.TGE is 1, when they are taken to EL2 instead.
- From EL1 are taken to EL1.
- From EL2 are taken to EL2.
- From EL3 are taken to EL3.

The exception is reported in the ESR_ELx for the Exception level to which it is taken.

In an implementation that includes synchronous exception generation for floating-point exceptions in AArch64 state:

- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception bits in the event of such an exception. For more information see Combinations of floating-point exceptions on page D1-1901.

- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ESR_ELx reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported, however the element that is reported is identified in the ESR_ELx.

The AArch64.FPTrappedException() and FPProcessException() pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.
Combinations of floating-point exceptions

Many pseudocode functions perform floating-point operations, including FixedToFP(), FPAdd(), FPCmpare(), FPCmpareEQ(), FPCmpareGE(), FPCmpareGT(), FPDiv(), FPMax(), FPMin(), FPMul(), FPMulAdd(), FPRcipeEstimate(), FPRcipeStepFused(), FPRSqrtEstimate(), FPRcipeStepFused(), FPSqrt(), FPSqrt(), and FPToFixed(). All of these operations can generate floating-point exceptions.

Note

FPAbs() and FPNeg() are not classified as floating-point operations because:

- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:
  - NaN handling and the Default NaN on page A1-54.

More than one floating-point exception can occur on the same operation. The only combinations of floating-point exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other floating-point exceptions.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, a floating-point exception on one operation is treated as higher priority than a floating-point exception on another operation if the occurrence of the second floating-point exception depends on the result of the first operation. Otherwise, it is CONSTRAINED UNPREDICTABLE which floating-point exception is treated as higher priority, where the exception prioritization might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the FPSR to be set to 1.

When a floating-point exception is trapped:

- It is IMPLEMENTATION DEFINED whether the FPSR is restored when the trapped floating-point exception is taken. If the FPSR is not restored then, then it is CONSTRAINED UNPREDICTABLE which untrapped floating-point exception, if any, are indicated by the corresponding FPSR cumulative exception bits having the value 1.
- In the ESR_ELx for the Exception level to which the trapped exception is taken, the value of the floating-point exception trapped bit for the highest priority trapped floating-point exception must be 1.

In this ESR_ELx:

- The value of the floating-point exception trapped bit for any other untrapped floating-point exception generated by the same operation must be 0. This applies to both higher priority and lower priority untrapped floating point exceptions.
- The value of the floating-point exception trapped bit for any lower priority trapped floating-point exception generated by the same operation might be 1, but the architecture does not require this.

For trapped floating-point exceptions from Advanced SIMD instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction. The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD operation.

Note

An implementation might provide information about a lower priority or untrapped floating-point exceptions in an IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.
D1.14 Asynchronous exception types, routing, masking and priorities

In the ARMv8-A architecture, asynchronous exceptions that are taken to AArch64 state are also known as interrupts.

There are two types of interrupts:

**Physical interrupts** Are signals sent to the PE from outside the PE. They are:
- SError. System Error.
- IRQ.
- FIQ.

**Virtual interrupts** Are interrupts that software executing at EL2 can enable and make pending. A virtual interrupt is taken from Non-secure EL0 or Non-secure EL1 to Non-secure EL1.

Virtual interrupts have names that correspond to the physical interrupts:
- vSError.
- vIRQ.
- vFIQ.

--- Note ---

- For information about how virtual interrupts might be used see Virtual interrupt usage model on page D1-1858.
- The SError interrupt replaces the ARMv7 asynchronous abort. The new name better describes the nature of the exception, and means that, in AArch64 state, it is categorized as a unique exception class, with EC encoding 0x2F.

An External abort generated by the memory system might be taken asynchronously using the SError interrupt. These SError interrupts always behave as edge-triggered interrupts. An implementation might include other sources of SError interrupt. It is IMPLEMENTATION DEFINED whether these other sources are edge-triggered or level-sensitive. See also External aborts on page D3-2074.

Each physical interrupt type can be assigned a target Exception level of EL1, EL2 or EL3, as shown in Asynchronous exception routing on page D1-1903.

When an interrupt occurs:

- On taking an SError or a vSError interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is updated to describe an SError interrupt. When the RAS Extension is implemented, the exception syndrome for the vSError interrupt is taken from the values in the VSESR_EL2 register. See Exception classes and the ESR_ELx syndrome registers on page D1-1876, and the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.
- On taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is not updated.

The remainder of this section contains the following:
- Asynchronous exception routing on page D1-1903.
- Asynchronous exception masking on page D1-1905.
- Virtual interrupts on page D1-1907.
- Prioritization and recognition of interrupts on page D1-1908.
- Taking an interrupt or other exception during a multiple-register load or store on page D1-1909.
D1.14.1 Asynchronous exception routing

The following tables show the routing of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see Table D1-12.
- For implementations that include EL3 but not EL2, see Table D1-13 on page D1-1904.
- For implementations that include EL2 but not EL3, see Table D1-14 on page D1-1904.

In the tables:

- **C**: Indicates that the interrupt is not taken, regardless of the Process state interrupt mask.
- **n/a**: Not applicable:
  - In an implementation that includes EL3, the PE cannot be executing at EL2 when the value of SCR_EL3.NS is 0.
  - In an implementation that includes EL2, the PE cannot be executing at Non-secure EL1 when the value of HCR.TGE is 1.

**HCR**

In Table D1-12, including in the table footnote:

- When EL2 is using AArch64 HCR refers to the AArch64 register HCR_EL2.
- When EL2 is using AArch32 HCR refers to the AArch32 register HCR.

When the Effective value of HCR.{E2H, TGE} is:

- **{0, 1}**: The Effective value of each of the HCR.{AMO, IMO, FMO} fields is 1.
- **{1, 1}**: The Effective value of each of the HCR.{AMO, IMO, FMO} fields is 0.

</tbody>
</table>
### D1.14.2 Asynchronous exception masking

When an interrupt is masked, it means that it cannot be taken. Instead, it remains pending.

When executing in AArch64 state, interrupts are masked implicitly when the target Exception level of the interrupt is lower than the current Exception level.

In addition, interrupts can be masked when the target Exception level is the current Exception level. The controls for this are:

<table>
<thead>
<tr>
<th>SError</th>
<th>PSTATE.A</th>
</tr>
</thead>
<tbody>
<tr>
<td>IRQ</td>
<td>PSTATE.I</td>
</tr>
<tr>
<td>FIQ</td>
<td>PSTATE.F</td>
</tr>
</tbody>
</table>

When the target Exception level is higher than the current Exception level:

- If the target Exception level is EL2 or EL3, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL1, the interrupt can be masked by the PSTATE.{A, I, F} bits.

**Note**

- The ability to execute in EL0 with interrupts to EL1 masked is required by some user level driver code.
- The PSTATE.{A, I, F} bits can mask both physical interrupts and virtual interrupts.
- The ARMv8-A architecture does not support Non-maskable FIQ (NMFI) operations. This means that it does not provide a configuration option to override the masking of FIQs by PSTATE.F.

On taking any exception to an Exception level using AArch64, all of PSTATE.{A, I, F} are set to 1, masking all interrupts that target that Exception level.

The following tables show the masking of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see Table D1-15 on page D1-1906.
- For implementations that include EL3 but not EL2, see Table D1-16 on page D1-1906.
- For implementations that include EL2 but not EL3, see Table D1-17 on page D1-1907.

For the masking of virtual interrupts, see *Virtual interrupts* on page D1-1907.

In the tables:

- **A** When the interrupt is asserted it is taken regardless of the value of the Process state interrupt mask.
- **B** When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is taken. If the value of the mask is 0 the interrupt is taken.
- **C** When the interrupt is asserted it is not taken, regardless of the value of the Process state interrupt mask.
- **-** When the value of SCR_EL3.RW is 0, EL2 is using AArch32, and there is no HCR.E2H bit.
- **n/a** Not applicable:
  - In an implementation that includes EL3, the PE cannot be executing at EL2 when the value of SCR_EL3.NS is 0.
  - The PE cannot be executing at Non-secure EL1 when the value of HCR.TGE is 1.

**HCR**

In Table D1-15 on page D1-1906, including in the table footnote:

- When EL2 is using AArch64 HCR refers to the AArch64 register HCR_EL2.
- When EL2 is using AArch32 HCR refers to the AArch32 register HCR.

When the value of HCR.TGE is 1, the virtual exceptions are disabled. When the *Effective value* of HCR.{E2H, TGE} is:

- \{0, 1\} The *Effective value* of each of the HCR.{AMO, IMO, FMO} fields is 1.
- \{1, 1\} The *Effective value* of each of the HCR.{AMO, IMO, FMO} fields is 0.
### Table D1-15 Physical interrupt target and masking when both EL3 and EL2 are implemented

<table>
<thead>
<tr>
<th>SCR_EL3</th>
<th>HCR</th>
<th>Effect of the interrupt mask when executing at:</th>
</tr>
</thead>
<tbody>

<td>0</td>
<td>x</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>x</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>

\(^a\) When the implementation does not include ARMv8.1-VHE, the HCR_EL2.E2H field is not implemented and behavior is as if the value of E2H is 0.

\(^b\) In these cases, the exception is taken from an Exception level using AArch32 to an Exception level using AArch32, and therefore the masking rules defined in Asynchronous exception masking controls on page G1-4653 apply.

### Table D1-16 Physical interrupt target and masking when EL3 is implemented and EL2 is not implemented

</tbody>
</table>
D1.14 Asynchronous exception types, routing, masking and priorities

D1.14.3 Virtual interrupts

When the value of HCR_EL2.TGE is 0, setting an HCR_EL2.{FMO, IMO, AMO} routing control bit to 1 enables the corresponding virtual interrupt. When the value of HCR_EL2.TGE is 1 all virtual interrupts are disabled.

Virtual interrupts can only be taken from Non-secure EL0 or Non-secure EL1 to Non-secure EL1. When a virtual interrupt type is enabled, that type of interrupt can be generated by:

- Software setting the corresponding virtual interrupt pending bit, HCR_EL2.{VSE, VI, VF}, to 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the ARM Generic Interrupt Controller Architecture Specification.

Note

For a usage model for virtual interrupts, see Virtual interrupt usage model on page D1-1858.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the ISR_EL1.

Each virtual interrupt type can be masked when execution is in Non-secure EL1 or EL0, by using the same Process State mask bits that mask the physical interrupts, PSTATE.{A, I, F}.

When execution is in Secure state, or at EL2, all types of virtual interrupt are always masked.

Table D1-18 summarizes the bits that enable virtual interrupts and the bits that cause virtual interrupts to be pending.

Table D1-17 Physical interrupt target and masking when EL3 is not implemented and EL2 is implemented

<table>
<thead>
<tr>
<th>HCR_EL2</th>
<th>Target Exception level</th>
<th>Effect of the interrupt mask when executing at:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL0</td>
<td>EL1</td>
</tr>
<tr>
<td>E2H=0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>E2H=1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

a. If the implementation does not include ARMv8.1-VHE, the HCR.E2H field is not implemented and behavior is as if the value of E2H is 0.

Table D1-18 HCR_EL2 interrupt control bits

<table>
<thead>
<tr>
<th>Virtual interrupt type</th>
<th>Enable control(^a)</th>
<th>Cause a virtual interrupt to be pending</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSError</td>
<td>HCR_EL2.AMO</td>
<td>HCR_EL2.VSE</td>
</tr>
<tr>
<td>vIRQ</td>
<td>HCR_EL2.IMO</td>
<td>HCR_EL2.VI</td>
</tr>
<tr>
<td>vFIQ</td>
<td>HCR_EL2.FMO</td>
<td>HCR_EL2.VF</td>
</tr>
</tbody>
</table>

a. Applies only when the value of HCR_EL2.TGE is 0, otherwise the virtual interrupts are disabled.

On taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in the HCR_EL2 retains its state.
On taking a vSError interrupt, HCR_EL2.VSE is cleared to 0.

Note
This means that if the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing at EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

Taking a vSError interrupt to an Exception level using AArch64 updates ESR_EL1 with the encoding for an SError interrupt. For the encoding, see Exception classes and the ESR_ELx syndrome registers on page D1-1876. When the RAS Extension is implemented, the exception syndrome for the vSError interrupt is taken from the values in the VSER_EL2 register, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile. Taking a vIRQ or a vFIQ interrupt to an Exception level using AArch64 does not update the ESR_EL1.

The following table shows the masking of virtual interrupts when the highest implemented Exception level is using AArch64. In the table:

| B | When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken. |
| C | When the interrupt is asserted it is not taken, regardless of the value of the Process state mask. |
| n/a | Not applicable: |

- In an implementation that includes EL3, the PE cannot be executing at EL2 when the value of SCR_EL3.NS is 0.
- The PE cannot be executing at Non-secure EL1 when the value of HCR.TGE is 1.

HCR
In Table D1-19, including in the table footnote:
- When EL2 is using AArch64 HCR refers to the AArch64 register HCR_EL2.
- When EL2 is using AArch32 HCR refers to the AArch32 register HCR.

When the value of HCR.TGE is 1, the virtual exceptions are disabled.

When the Effective value of HCR.{E2H, TGE} is:

{0, 1} The Effective value of each of the HCR.{AMO, IMO, FMO} fields is 1.

{1, 1} The Effective value of each of the HCR.{AMO, IMO, FMO} fields is 0.

Table D1-19 Virtual interrupt masking

</tr>
</tbody>
</table>

a. If EL2 is using AArch32 or the implementation does not include ARMv8.1-VHE, the HCR.E2H field is not implemented and behavior is as if the value of E2H is 0.

D1.14.4 Prioritization and recognition of interrupts

The prioritization of interrupts, including virtual interrupts, is IMPLEMENTATION DEFINED.

Note
As indicated at the start of Asynchronous exception types, routing, masking and priorities on page D1-1902, in AArch64 state all possible asynchronous exceptions are defined as interrupts.
Any interrupt that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event, provided that the pending interrupt is not masked:

- Execution of an ISB instruction.
- Exception entry.
- Exception return.
- Exit from Debug state.

--- Note ---
- If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define whether the PE takes the interrupt or the synchronous exception first.
- The ISR_EL1 identifies any pending interrupts.
- Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

An error synchronization event defines additional requirements for taking an SError interrupt, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

In the absence of a specific requirement to take an interrupt, the architecture only requires that unmasked pending interrupts are taken in finite time.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken then it must be taken before the first Context synchronization event after the interrupt was changed to not pending.

### D1.14.5 Taking an interrupt or other exception during a multiple-register load or store

In AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.

If an interrupt, or another exception, is taken from AArch64 during the execution of an instruction that performs a sequence of memory accesses, rather than a single single-copy atomic access, then:

- For a load, any register being loaded by the instruction other than ones used in the generation of the address by the instruction, can contain an UNKNOWN value. Registers used in the generation of the address are restored to their initial value.
- For a store, any data location being stored to by the instruction can contain an UNKNOWN value.
- For either a load or a store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

--- Note ---
- This interrupt behavior is in contrast to behavior in AArch32 state, when interrupts cannot be taken during a sequence of memory accesses caused by a single load or store instruction.
- In both Execution states, synchronous data abort exceptions can be taken during the execution of an instruction that performs a sequence of memory accesses.
- Software must avoid using multiple-register load and store instructions for accesses to Device memory, particularly to Device memory with the non-Gathering attribute, because an exception taken during the load or store can result in repeated accesses.
D1.15 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch64 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an instruction enable, an instruction disable, or a trap control:

Instruction enables and instruction disables
Enable or disable the use of one or more particular instructions at a particular Exception level and Security state.
When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

Trap controls
A trap control determines whether one or more particular instructions, whenever executed at a particular Exception level, are trapped.
A trapped instruction generates a Trap exception.

For trap controls provided by:
- **EL1** Trap exceptions are taken to EL1, unless routed from Non-secure EL0 to EL2 because HCR_EL2.TGE is 1 as described in Routing exceptions from Non-secure EL0 to EL2 on page D1-1895. For descriptions of these controls see EL1 configurable controls on page D1-1911.
- **EL2** Trap exceptions are taken to EL2. For descriptions of these controls see EL2 configurable controls on page D1-1920.
- **EL3** Trap exceptions are taken to EL3. For descriptions of these controls see EL3 configurable controls on page D1-1942.

---

**Note**
The definitions of traps and enables and disables overlap, and the classification of some controls is historical. In AArch64 state, the most significant characteristic of an exception report is the ESR_ELx.EC value with which it is reported. Describing a register control field as an instruction enable, an instruction disable, or a trap control, gives no indication of how an exception that is generated as a consequence of the value of that field is handled or reported.

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if both of the following apply:

- The instruction generating the exception does not also generate a higher priority exception. Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895 defines the prioritization of different exceptions on the same instruction.
- The instruction is not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state it is executed in. UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of these controls, but the architecture does not require them to do so.

Exceptions generated as a result of these controls are synchronous exceptions.

Exceptions are reported in the ESR_ELx, with an EC value that indicates the Exception class. and:

- Many cases, including all traps, are reported with a non-zero EC value and an associated syndrome.
- Some cases where an instruction is UNDEFINED are reported with an EC value 0x00, the value for an exception for an unknown or uncategorized reason, and in these cases no syndrome is provided. ISS encoding for exceptions with an unknown reason on page D10-2441 identifies the cases that are reported with EC value 0x00.
Table D1-8 on page D1-1877 lists the EC values that are used for exceptions that result from traps, enables, and disables.

--- Note ---
- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, SCTLR_EL1.DZE is a trap control even though DZE means DC ZVA Enable.
- In addition to the controls described in this section, a routing control, HCR_EL2.TGE, can be used to route exceptions from EL0 to EL2. See Routing exceptions from Non-secure EL0 to EL2 on page D1-1895.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

This section is organized as follows:
- Register access instructions.
- EL1 configurable controls.
- EL2 configurable controls on page D1-1920.
- EL3 configurable controls on page D1-1942.

D1.15.1 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:
- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

D1.15.2 EL1 configurable controls

These controls are in _EL1 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL1.M[4] indicates which Execution state the exception was taken from.

Table D1-20 shows the _EL1 System registers that contain these controls.

Traps to EL1 of EL0 execution of cache maintenance instructions

SCTLR_EL1.UCI traps EL0 execution of cache maintenance instructions to EL1:
1. EL0 execution of cache maintenance instructions is not trapped to EL1.
0. Any attempt to execute a cache maintenance instruction at EL0 is trapped to EL1.

Table D1-23 shows the instructions that are trapped to EL1, and how the exceptions are reported in ESR_EL1:

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>DC CVAU, DC CIVAC, DC CVAC, DC CVAP, IC IVAU</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
<td></td>
</tr>
</tbody>
</table>

AArch32 state n/a n/a

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to the CTR_EL0

SCTLR_EL1.UCT traps EL0 accesses to the CTR_EL0 to EL1:
1. EL0 accesses to the CTR_EL0 are not trapped to EL1.
0. EL0 accesses to the CTR_EL0 are trapped to EL1.

Table D1-24 shows how the exceptions are reported in ESR_EL1:

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Register</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTR_EL0</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
<td></td>
</tr>
</tbody>
</table>

AArch32 state n/a n/a

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 execution of WFE and WFI instructions

SCTLR_EL1.{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to EL1:

SCTLR_EL1.nTWE
1. EL0 execution of WFE instructions is not trapped to EL1.
0. Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

SCTLR_EL1.nTWI
1. EL0 execution of WFI instructions is not trapped to EL1.
0. Any attempt to execute a WFI instruction at EL0 is trapped EL1, if the instruction would otherwise have caused the PE to enter a low-power state.
Table D1-25 shows how the exceptions are reported in ESR_EL1:

Table D1-25 Instructions trapped to EL1 when SCTLR_EL1.(nTWE, nTWI) are 0

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTLR_EL1.nTWE</td>
<td>Both Execution states</td>
<td>WFE, WFI</td>
<td>Trapped WFE or WFI instruction, using EC value 0x01</td>
</tr>
<tr>
<td>SCTLR_EL1.nTWI</td>
<td>WFE</td>
<td>WFI</td>
<td></td>
</tr>
</tbody>
</table>

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

**Note**

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait for Event mechanism and Send event on page D1-1954.*
- *Wait For Interrupt on page D1-1957.*

**Traps to EL1 of EL0 execution of DC ZVA instructions**

SCTLR_EL1.DZE traps EL0 execution of DC ZVA instructions to EL1:

1 EL0 execution of DC ZVA instructions is not trapped to EL1.

0 Any attempt to execute a DC ZVA instruction at EL0 is trapped to EL1. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not implemented.

Table D1-26 shows how the exceptions are reported in ESR_EL1:

Table D1-26 Instruction trapped to EL1 when SCTLR_EL1.DZE is 0

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>DC ZVA</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

**Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks**

SCTLR_EL1.UMA traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1:

1 EL0 execution of MSR or MRS instructions that access the DAIF is not trapped to EL1.

0 Any attempt at EL0 to execute an MSR or an MRS instruction that accesses the DAIF is trapped to EL1.
Table D1-27 shows how the exceptions are reported in ESR_EL1:

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled instructions</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>MRS, MSR (register), MSR (immediate), that access the DAIF</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18a</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

**Disabling or enabling EL0 use of AArch32 deprecated functionality**

Table D1-28 shows the deprecated AArch32 functionality that might have disable controls in the SCTLR_EL1:

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

These SCTLR_EL1 controls apply only to execution at EL0 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL0 using AArch32. Table D1-28 shows how the exceptions are reported in ESR_EL1:

**Table D1-28 EL1 controls for disabling and enabling EL0 use of AArch32 deprecated functionality**

<table>
<thead>
<tr>
<th>Deprecated AArch32 functionality</th>
<th>Instruction enable or disable in the SCTLR_EL1</th>
<th>Disabled instructions</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETEN0 instructions</td>
<td>SEDb</td>
<td>SETEND instructions</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>Some uses of IT instructions</td>
<td>ITDc</td>
<td>See the SCTLR_EL1.IT description</td>
<td></td>
</tr>
<tr>
<td>Accesses to the CP15DMB, CP15DSB, and CP15ISB barrier instructions</td>
<td>CP15BEND</td>
<td>%CR accesses to the CP15DMB, CP15DSB, and CP15ISB instructions</td>
<td></td>
</tr>
</tbody>
</table>

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, the exception is routed to EL2 and reported in ESR_EL2 using the EC value shown in the table.

---

**Note**

- The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.
- The SCTLR provides similar controls that apply when EL1 is using AArch32, and the HSCTLR provides similar controls that apply when EL2 is using AArch32.

**Traps to EL1 of EL0 and EL1 System register accesses to the trace registers**

CPACR_EL1.TTA traps EL0 and EL1 System register accesses to the trace registers to EL1.

1. EL0 and EL1 System register accesses to the trace registers are trapped to EL1.
2. EL0 and EL1 System register accesses to the trace registers are not trapped to EL1.
Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and the resulting exception is higher priority than a CPACR_EL1.TTA Trap exception.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page D1-1911.

Table D1-29 shows the registers for which accesses are trapped to EL1 when CPACR_EL1.TTA is 1, and how the exceptions are reported in ESR_EL1:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>All implemented trace registers</td>
<td>Trapped AArch64 MSR, MR5, or system instruction, using EC value 0x18.(^a)</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>All implemented trace registers</td>
<td>For accesses using:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.(^a)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.(^a)</td>
</tr>
</tbody>
</table>

\(^a\) If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality

When EL1 is using AArch64, CPACR_EL1.FPEN traps EL0 and EL1 accesses to the SIMD and floating-point registers to EL1:

00 Causes any instructions in EL0 or EL1 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped.

01 Causes any instructions in EL0 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped, but does not cause any instruction in EL1 to be trapped.

10 Causes any instructions in EL0 or EL1 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped.

11 Does not cause any instruction to be trapped.

Table D1-30 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL1:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0 and EL1 using AArch64, or EL0 using AArch64 only(^a).</td>
<td>FPCR, FPSCR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See The SIMD and floating-point registers, V0-V31 on page D1-1860.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07(^b)</td>
</tr>
<tr>
<td>EL0 using AArch32</td>
<td>FPSR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-4699.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07(^b)</td>
</tr>
</tbody>
</table>
Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers

MDSCR_EL1.TDCC traps EL0 accesses to the DCC registers to EL1:
1  EL0 accesses to the DCC registers are trapped to EL1.
0  EL0 accesses to the DCC registers are not trapped to EL1.

Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

Traps of AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0 are ignored in Debug state.

Table D1-31 shows the accesses that are trapped, and how the exceptions are reported in ESR_EL1:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
</table>
| AArch64 state | Accesses to the MDCCSR_EL0, DBGDTR_EL0, DBGDTRTX_EL0 and DBGDTRRX_EL0 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
| AArch32 state | • MRC of DBGDSCRint, DBGDTRRXint, and, if implemented, DBGDIR, DBGSR and DBGSRAR.  
• MCR to DBGDTRXint.  
• LDC access to DBGDTRTXint.  
• STC access to DBGDTRRXint.  
If implemented, MRR of DBGDSAR and DBGDRAR. | Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to the Generic Timer registers

CNTKCTL_EL1.[EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN] trap EL0 accesses to the Generic Timer registers to EL1, as follows:
• CNTKCTL_EL1.EL0PTEN traps EL0 accesses to the physical timer registers.
• CNTKCTL_EL1.EL0VTEN traps EL0 accesses to the virtual timer registers.
• CNTKCTL_EL1.EL0PCTEN traps EL0 accesses to the frequency register and physical counter register.
• CNTKCTL_EL1.EL0VCTEN traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:
1  EL0 accesses are not trapped to EL1.
0  EL0 accesses are trapped to EL1.

Accesses to the frequency register, CNTFRQ_EL0 or CNTFRQ, are only trapped if CNTKCTL_EL1.EL0PCTEN and CNTKCTL_EL1.EL0VCTEN are both 0.
Table D1-32 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL1:

```
<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>EL0PTEN</td>
<td>CNTP_CTL_EL0, CNTP_CVAL_EL0, CNTP_TVAL_EL0</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18a</td>
</tr>
<tr>
<td></td>
<td>EL0VTEN</td>
<td>CNTV_CTL_EL0, CNTV_CVAL_EL0, CNTV_TVAL_EL0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>EL0PCTEN</td>

<td></td>
</tr>
<tr>
<td></td>
<td>EL0VCTEN</td>
<td>CNTFRQ_EL0, CNTVCT_EL0</td>
<td></td>
</tr>
<tr>
<td>AArch32 state</td>
<td>EL0PTEN</td>
<td>CNTP_CTL, CNTP_CVAL, CNTP_TVAL</td>
<td></td>
</tr>
<tr>
<td></td>
<td>EL0VTEN</td>
<td>CNTV_CTL, CNTV_CVAL, CNTV_TVAL</td>
<td>For accesses using:</td>
</tr>
<tr>
<td></td>
<td>EL0PCTEN</td>
<td>CNTPCT</td>
<td>• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03a</td>
</tr>
<tr>
<td></td>
<td>EL0VCTEN</td>
<td>CNTPCT</td>
<td>• MCR or MRRC instructions, trapped MCR or MRRC access (coproc==0b1111), using EC value 0x04a</td>
</tr>
</tbody>
</table>
```

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

**Traps to EL1 of EL0 accesses to Performance Monitors registers**

PMUSERENR_EL0.\{ER, CR, SW, EN\} trap EL0 accesses to the Performance Monitors registers to EL1. For each of these controls:

1. EL0 accesses are not trapped to EL1.
0. EL0 accesses are trapped to EL1.

For those Performance Monitors registers that more than one PMUSERENR_EL0.\{ER, CR, SW, EN\} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.
Table D1-33 shows:
- The registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.
- How the exceptions are reported in ESR_EL1.

**Table D1-33 Register accesses trapped to EL1 when disabled from EL0**

</tr>
</tbody>
</table>

^a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

^b. The EL0 access is trapped only if the corresponding EL1 accesses is permitted. For example, the PMSWINC_EL0 and PMSWINC registers are WO at EL1, and therefore, when the value of EN is 0:
- Write accesses to these registers from EL0 are trapped.
- Read accesses to these registers from EL0 are UNDEFINED, because read accesses to the registers from EL1 are UNDEFINED.
Enabling use of the Pointer authentication instructions, EL1&0 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

Each of the SCTLR_EL1.{EnDA, EnDB, EnIA, EnIB} fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL1&0 translation regime. For more information see System register control of pointer authentication on page D4-2088.

--- Note ---
These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.

Disabling Address tagging for instruction accesses, EL1&0 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

When a TCR_EL1.{TBI0, TBI1} field enables the use of address tagging for the EL1&0 translation regime, the corresponding TCR_EL1.{TBID0, TBID1} field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information see Address tagging in AArch64 state on page D4-2084.

--- Note ---
These controls determine the scope of address tagging. They never cause an exception to be generated.

D1.15.3  EL2 configurable controls

These controls are in _EL2 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL2.M[4] indicates which Execution state the exception was taken from.

These controls are ignored in Secure state.

Table D1-34 shows the _EL2 System registers that contain these controls.

<table>

  - Instructions that fail their Condition code check on page G1-4713.
  - Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-4713.

### Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers

**HCR_EL2.{TRVM, TVM}** trap Non-secure EL1 accesses to the virtual memory control registers to EL2:

**HCR_EL2.TRVM**, for read accesses:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Non-secure EL1 reads of the virtual memory control registers are trapped to EL2.</td>
</tr>
<tr>
<td>0</td>
<td>Non-secure EL1 reads of the virtual memory control registers are not trapped to EL2.</td>
</tr>
</tbody>
</table>

**HCR_EL2.TVM**, for write access:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Non-secure EL1 writes to the virtual memory control registers are trapped to EL2.</td>
</tr>
<tr>
<td>0</td>
<td>Non-secure writes to the virtual memory control registers are not trapped to EL2.</td>
</tr>
</tbody>
</table>

Table D1-37 on page D1-1923 shows:

- The registers for which reads are trapped to EL2 when **HCR_EL2.TRVM** is 1.
- The registers for which writes are trapped to EL2 when **HCR_EL2.TVM** is 1.
How the exceptions are reported in ESR_EL2.

Table D1-37 Register read and write accesses trapped when HCR_EL2.(TRVM, TVM) are 1

<table>

<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03. Trapped MCR or MRC access (coproc==0b1111), using EC value 0x04.</td>
</tr>
</tbody>
</table>

Note

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.

Disabling Non-secure state execution of HVC instructions

HCR_EL2.HCD disables Non-secure state execution of HVC instructions:

1  
HVC instructions are UNDEFINED at EL2 and Non-secure EL1, and any resulting exception is taken from the current Exception level to the current Exception level.

0  
HVC instruction execution is enabled at EL2 and Non-secure EL1.

Note

HVC instructions are always UNDEFINED at EL0.

HCR_EL2.HCD is only implemented if EL3 is not implemented. Otherwise, it is RES0.

Table D1-38 shows how the exceptions are reported in ESR_ELx:

Table D1-38 Instruction disabled when HCR_EL2.HCD is 1

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled instruction</th>
<th>Syndrome reporting in ESR_ELx</th>

</table>

Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions

HCR_EL2.TDZ traps Non-secure EL0 and EL1 execution of DC ZVA instructions to EL2:

1  
Any attempt to execute a DC ZVA instruction at Non-secure EL0 or EL1 is trapped to EL2. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not implemented.

0  
Non-secure EL0 and EL1 execution of DC ZVA instructions is not trapped to EL2.
Table D1-39 shows how the exceptions are reported in ESR_EL2:

### Table D1-39 Instruction trapped to EL1 when HCR_EL2.TDZ is 0

**Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions**

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

HCR_EL2.TTLB traps Non-secure EL1 execution of TLB maintenance instructions to EL2:

| 0 | Any attempt to execute a TLBI instruction at Non-secure EL1 is trapped to EL2. |
| 1 | Non-secure EL1 execution of TLBI instructions is not trapped to EL2. |

Table D1-40 shows the instructions that are trapped, and how the exceptions are reported in ESR_EL2:

### Table D1-40 Instructions trapped to EL2 when HCR_EL2.TTLB is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>TLBI VMALLE1IS, TLBI VAE1IS, TLBI ASIDE1IS, TLBI VAAE1IS, TLBI VALE1IS, TLBI VAALE1IS, TLBI VMALLE1, TLBI VALE1, TLBI VAAE1, TLBI VAALE1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBMIMVAIS, TLBMIVALIS, TLBIMVAALIS, ITLBIALL, ITLBMVA, ITLBIASID, DTLBIALL, DTLBMVA, DTLBIASID, TLBIALL, TLBMVA, TLBIASID, TLBMIMVA, TLBMIVAL, TLBMIMVAAL</td>
<td>Trapped MCR or MRC access (coproc == 0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**Note**

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see:
- *TLB maintenance instructions* on page D4-2209, for the AArch64 state instructions.
- *The scope of TLB maintenance instructions* on page G4-4924, for the AArch32 state instructions.

**Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions**

HCR_EL2.\{TSW, TPC, TPU\} trap cache maintenance instructions to EL2 as follows:

| 0 | The control has no effect on the execution of cache maintenance instructions. |
| 1 | Any attempt to execute a corresponding cache maintenance instruction at Non-secure EL1, or at Non-secure EL0 if permitted by SCTLR_EL1.UCI, is trapped to EL2. |

### Table D1-41 Controls for trapping cache maintenance instructions to EL2

<table>
<thead>
<tr>

<tr>
<td>AArch32 state</td>
<td>ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU</td>
<td>Trapped MCR or MRC access (coproc == 0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

--- **Note**

**IC IALLUIS** and **IC IALLU** are always UNDEFINED at EL0 using AArch64.

**ICIMVAU, ICIALLU, ICIALLUIS, and DCCMVAU** are always UNDEFINED at EL0 using AArch32.
For more information about these instructions, see:

- Cache maintenance instructions, and data cache zero on page C5-333 for the AArch64 instructions.
- Cache maintenance system instructions on page K13-6613 for the AArch32 instructions.

### Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register

HCR_EL2.TACR traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to EL2.</td>
</tr>
<tr>
<td>0</td>
<td>Non-secure EL1 accesses to the Auxiliary Control Registers are not trapped to EL2.</td>
</tr>
</tbody>
</table>

Table D1-45 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2:

#### Table D1-45 Register accesses trapped to EL2 when HCR_EL2.TACR is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>ACTLR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>ACTLR and, if implemented, ACTLR2.</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

---

**Note**

- The ACTLR_EL1, ACTLR, and ACTLR2 are not accessible at EL0.
- The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

---

### Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

HCR_EL2.TIDCP traps the execution of System register access instructions that access these registers, as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>At Non-secure EL1, any attempt to execute a System register access instruction with a reserved register encoding is trapped to EL2. At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute System register access instructions with reserved register encodings are:</td>
</tr>
<tr>
<td></td>
<td>- Trapped to EL2.</td>
</tr>
<tr>
<td></td>
<td>- UNDEFINED, and any resulting exception is taken to EL1.</td>
</tr>
<tr>
<td>0</td>
<td>Non-secure EL0 and EL1 System register access instructions with reserved register encodings are not trapped to EL2.</td>
</tr>
</tbody>
</table>
Table D1-46 shows the register encodings for which accesses are trapped, and how the exceptions are reported in ESR_EL2:

### Table D1-46 Encodings trapped to EL2 when HCR_EL2.TIDCP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register encodings</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AArch64 state</strong></td>
<td>Any access to any of the encodings described in <em>Reserved encodings for IMPLEMENTATION DEFINED registers</em> on page D9-2345.</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
</tbody>
</table>
| **AArch32 state** | An access to any of the following encodings:  
  - CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}.  
  - CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}.  
  - CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}. | Trapped MCR or MRC access (coproc == 0b1111), using EC value 0x83 |

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

--- **Note** ---

- ARM expects the trapping of Non-secure EL0 accesses to these functions to EL2 to be unusual, and used only when the hypervisor is virtualizing EL0 operation. ARM strongly recommends that unless the hypervisor must virtualize EL0 operation, a Non-secure EL0 access to any of these functions is UNDEFINED, as it would be if the implementation did not include EL2. The PE then takes any resulting exception to Non-secure EL1.

- The trapping of accesses to these registers from Non-secure EL1 is higher priority than an exception resulting from the register access being UNDEFINED.

### Traps to EL2 of Non-secure EL1 execution of SMC instructions

**HCR_EL2.TSC** traps Non-secure EL1 execution of SMC instructions to EL2:

1. Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of SCR_EL3.SMD.

0. Non-secure EL1 execution of SMC instructions is not trapped to EL2.

If EL3 is not implemented, HCR_EL2.TSC is RES0.

Table D1-47 shows how the exceptions are reported in ESR_EL2:

### Table D1-47 SMC Instruction trapped to EL2 when HCR_EL2.TSC is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AArch64 state</strong></td>
<td><em>SMC</em> on page C6-864</td>
<td>Trapped SMC instruction execution in AArch64 state, using EC value 0x17</td>
</tr>
<tr>
<td><strong>AArch32 state</strong></td>
<td><em>SMC</em> on page F5-3683</td>
<td>Trapped SMC instruction execution in AArch32 state, using EC value 0x13</td>
</tr>
</tbody>
</table>

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their Condition code check, in the same way as with traps on other conditional instructions.

For more information about SMC instructions, see *SMC* on page C6-864.
Note

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are UNDEFINED at EL0.
- HCR_EL2.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap exceptions and SMC exceptions have different preferred return addresses.

Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers

Other than the MIDR_EL1, MPIDR_EL1, and PMCR_EL0.N, the ID registers are divided into groups, with a trap control in the HCR_EL2 for each group.

Table D1-48 ID register groups

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Register group</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR_EL2.TID0</td>
<td>ID group 0, Primary device identification registers on page D1-1929</td>
</tr>
<tr>
<td>HCR_EL2.TID1</td>
<td>ID group 1, Implementation identification registers on page D1-1930</td>
</tr>
<tr>
<td>HCR_EL2.TID2</td>
<td>ID group 2, Cache identification registers on page D1-1930</td>
</tr>
<tr>
<td>HCR_EL2.TID3</td>
<td>ID group 3, Detailed feature identification registers on page D1-1930</td>
</tr>
</tbody>
</table>

These controls trap register accesses to EL2, as follows:

**HCR_EL2.TID0**

0  This control has no effect on Non-secure EL1 reads of the ID group 0 registers.
1  Any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to EL2.

**HCR_EL2.TID1**

0  This control has no effect on Non-secure EL1 reads of the ID group 1 registers.
1  Any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to EL2.

**HCR_EL2.TID2**

0  This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.
1  Any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the CSSEL or CSSEL_EL1, is trapped to EL2.

**HCR_EL2.TID3**

0  This control has no effect on Non-secure EL1 reads of the ID group 3 registers.
1  Any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to EL2.
For the MIDR_EL1 and MPIDR_EL1, and for PMCR_EL0.N, the architecture provides read/write aliases. The original register becomes accessible only from EL2 or Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

Note
- If the optional Performance Monitors Extension is not implemented, MDCR_EL2.HPMN is RES0 and PMCR_EL0 is reserved.
- MDCR_EL2.HPMN also affects whether a Performance Monitors counter can be accessed from Non-secure EL0 or EL1. See the register description of MDCR_EL2 for more information.
- PMCR_EL0 contains other fields that identify the implementation. For more information about trapping accesses to the PMCR_EL0, see Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1938.

ID group 0, Primary device identification registers

In:
- AArch64 state, there are no ID group 0 registers.
- AArch32 state, these registers identify some top-level implementation choices.

Table D1-50 shows the registers that are in ID group 0 for traps to EL2, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Group 0 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
<td>n/a</td>
<td>Trapped VMRS System register access, using EC value 0x08</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Traps from AArch32 state</th>
<th>Group 0 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSID</td>
<td>Trapped VMSR System register access (coproc==0b1110), using EC value 0x05</td>
<td></td>
</tr>
<tr>
<td>JIDR</td>
<td>Trapped VMSR System register access (coproc==0b1110), using EC value 0x05</td>
<td></td>
</tr>
</tbody>
</table>

Note
The FPSID is not accessible from EL0 using AArch32.

When the FPSID is accessible, a T32 or A32 VMRS FPSID, <rd> instruction is permitted but is ignored. The execution of this VMRS instruction execution is not trapped by the ID group 0 trap.
**ID group 1, Implementation identification registers**

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table D1-51 shows the registers that are in ID group 1 for traps to EL2, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 1 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>REVIDR_EL1, AIDR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>TCMTR, TLBTR, REVIDR, AIDR</td>
<td>Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 2, Cache identification registers**

These registers describe and control the cache implementation.

Table D1-52 shows the registers that are in ID group 2 for traps to EL2, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 2 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>CTR_EL0, CCSIDR_EL1, CLIDR_EL1, CSSELR_EL1, and, if implemented, CCSIDR2_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>CTR, CCSIDR, CLIDR, CSSELR, and, if implemented, CCSIDR2</td>
<td>Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 3, Detailed feature identification registers**

These registers provide detailed information about the features of the implementation.

--- **Note** ---

In AArch32 state, these registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See *The CPUID identification scheme* on page G7-5013.
Table D1-53 shows the registers that are in ID group 3 for traps to EL2, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Group 3 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1, ID_AFR0_EL1, ID_MMMFR0_EL1, ID_MMMFR1_EL1, ID_MMMFR2_EL1, ID_MMMFR3_EL1, ID_MMMFR4_EL1</td>
<td></td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, MVFR0_EL1, MVFR1_EL1, MVFR2_EL1, ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64MMFR2_EL1, ID_AA64MMFR3_EL1, ID_AA64AFR0_EL1, ID_AA64AFR1_EL1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

It is IMPLEMENTATION DEFINED whether HCR_EL2.TID3 traps MRS accesses to registers in the following range that are not already mentioned in this table:

- \( \text{OP0} = 3, \text{CRn} = c0, \text{OP1} = 0, \text{CRm} = \{c2-c7\}, \text{OP2} = \{0-7\} \).

| AArch32 state | MVFR0, MVFR1, MVFR2. | Trapped MRS System register access, using EC value 0x88 |

| Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions |

HCR_EL2.TWE trap Non-secure EL0 and EL1 execution of WFE and WFI instructions to EL2:

**HCR_EL2.TWE**

1 Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.

0 Non-secure EL0 or EL1 execution of WFE instructions is not trapped to EL2.

**HCR_EL2.TWI**

1 Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.

0 Non-secure EL0 or EL1 execution of WFI instructions is not trapped to EL2.
Table D1-54 shows how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR_EL2.TWE</td>
<td>Both Execution states</td>
<td>WFE</td>
<td>WFI</td>
</tr>
<tr>
<td>HCR_EL2.TWI</td>
<td>WFI</td>
<td>WFE or WFI instruction, using EC value 0x01</td>
<td></td>
</tr>
</tbody>
</table>

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

--- **Note** ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait for Event mechanism and Send event* on page D1-1954.
- *Wait For Interrupt* on page D1-1957.

### Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR

CPTR_EL2.TCPAC traps Non-secure EL1 accesses to the CPACR_EL1 or CPACR to EL2:

- **1** Non-secure EL1 accesses to the CPACR_EL1 or CPACR are trapped to EL2.
- **0** Non-secure EL1 accesses to the CPACR_EL1 or CPACR are not trapped to EL2.

Table D1-55 shows how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>CPACR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>CPACR</td>
<td>Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

--- **Note** ---

- The CPACR_EL1 or CPACR is not accessible at EL0.
- In ARMv7 and earlier versions of the ARM architecture, one function of the CPACR is as an ID register that identifies what coprocessor or conceptual coprocessor functionality is implemented. Legacy software might use this identification mechanism, and a hypervisor can use this trap to emulate this mechanism. For more information about this coprocessor model see *Background to the System register interface on page G1-4694.*

---
General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers

CPTR_EL2.TFP traps Non-secure accesses to SIMD and floating-point registers to EL2:

1. Any attempt at EL2, or Non-secure EL0 or EL1, to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL2.

0. Non-secure execution of instructions that access the SIMD or floating-point registers is not trapped to EL2.

Table D1-56 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2:

Table D1-56 Register accesses trapped to EL2 when CPTR_EL2.TFP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>

---

Traps to EL2 of Non-secure System register accesses to the trace registers

CPTR_EL2.TTA traps System register accesses to the trace registers to EL2. These traps are from Non-secure state, so are from all of:

- EL2.
- Non-secure EL0 and EL1.

When CPTR_EL2.TTA is:

1. Non-secure System register accesses to the trace registers are trapped to EL2.

0. Non-secure System register accesses to the trace registers are not trapped to EL2.

---

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a CPTR_EL2.TTA Trap exception.

- EL2 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see *Register access instructions* on page D1-1911.
Table D1-57 shows the registers for which accesses are trapped to EL2 when CPTR_EL2.TTA is 1, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>All implemented trace registers</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>
| AArch32 state | All implemented trace registers | Trapped MCR or MRC System register access (coproc == 0b1110), using EC value 0x05.  
  • Trapped MCR or MRC System register access (coproc == 0b1111), using EC value 0x0C. |

General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only

HSTR_EL2.{T0-T3, T5-T13, T15} trap accesses to the AArch32 System registers in the coproc == 0b1111 encoding space, by the register number, {c0-c3, c5-c13, c15} used for:

- The CRn argument used when accessing the register using an MCR or MRC instruction.
- The CRm argument used when accessing the register using an MCRR or MRRC instruction.

These traps are from AArch32 state only. They are from both:

- Non-secure EL1 using AArch32.
- Non-secure EL0 using AArch32.

When an HSTR_EL2.Tx trap control is:

1 Any AArch32 state Non-secure EL1 or EL0 access to the corresponding register is trapped to EL2.
0 AArch32 state Non-secure EL1 or EL0 accesses to the corresponding register are not trapped to EL2.

Table D1-58 shows the accesses that are trapped, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>MCR and MRC instructions, where CRn in the instruction identifies the trapped encodings in the (coproc == 0b1111) encoding space</td>
<td>Trapped MCR or MRC access (coproc == 0b1111), using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td>MCRR and MRRC instructions, where CRn in the instruction identifies the trapped encodings in the (coproc == 0b1111) encoding space</td>
<td>Trapped MCRR or MRRC access (coproc == 0b1111), using EC value 0x04</td>
</tr>
</tbody>
</table>

--- Note ---

HSTR_EL2[4, 14] is reserved, RES0. Although the Generic Timer AArch32 System registers are implemented in the coproc == 0b1111 encoding space and accessed using a CRn or CRm value of c14, EL2 does not provide a trap on accesses to the Generic Timer System registers.
**System registers in the \((\text{coproc}==0b1111)\) encoding space with IMPLEMENTATION DEFINED access permission from EL0**

For an AArch32 System register in the \((\text{coproc}==0b1111)\) encoding space, that is accessed using a CRn or CRm value that can be trapped by a \(\text{HSTR\_EL2}\cdot Tn\) control, if an access to the register from EL0 is UNDEFINED when the value of the corresponding \(\text{HSTR\_EL2}\cdot Tn\) trap control is 0, then when that \(\text{HSTR\_EL2}\cdot Tn\) trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure EL0 using AArch32:

- Generates a Trap exception that is taken to EL2.
- Is UNDEFINED and generates an exception that is taken to Non-secure EL1.

If the instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1, and Non-secure EL1 is using AArch64, the exception is reported in ESR\_EL1 as an exception for an unknown reason, using EC value 0x00.

--- **Note** ---

ARM expects that trapping to EL2 of Non-secure EL0 accesses to AArch32 System register in the \((\text{coproc}==0b1111)\) encoding space will be unusual, and used only when the hypervisor must virtualize EL0 operation. ARM recommends that, whenever possible, Non-secure EL0 accesses to the System registers behave as they would if the implementation did not include EL2. This means that, if the architecture does not support the Non-secure EL0 access, then the register access instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1.

--- **Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers** ---

MDCR\_EL2.\{TDRA, TDOSA, TDA\} trap Non-secure System register accesses to the debug registers to EL2, as follows:

- MDCR\_EL2.\{TDRA, TDOSA\} trap Non-secure EL0 and EL1 accesses.
- MDCR\_EL2.TDOSA traps Non-secure EL1 accesses.

--- **Note** ---

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. See Register access instructions on page D1-1911. Table D1-59 shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in ESR\_EL2:

**Table D1-59 Traps of Non-secure EL0 and EL1 accesses to debug registers**

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Subsection</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDCR_EL2.TDRA</td>
<td>Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers</td>
</tr>
<tr>
<td>MDCR_EL2.TDOSA</td>
<td>Trapping System register accesses to powerdown debug registers to EL2 on page D1-1936</td>
</tr>
<tr>
<td>MDCR_EL2.TDA</td>
<td>Trapping general System register accesses to debug registers to EL2 on page D1-1936</td>
</tr>
</tbody>
</table>

**Trapping System register accesses to Debug ROM registers to EL2**

MDCR\_EL2.TDRA traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to EL2:

1  Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2.
0  Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are not trapped to EL2.

This trap applies to Non-secure EL0 only if it is using AArch32.
Table D1-60 shows the register accesses that are trapped, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>MDRAR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>DBGDRAR, DBGDSAR</td>
<td>For accesses using:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.</td>
</tr>
</tbody>
</table>

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDRA is 1 other than for the purpose of a direct read.

*Trapping System register accesses to powerdown debug registers to EL2*

MDCR_EL2.TDOSA traps Non-secure EL1 System register accesses to the powerdown debug registers to EL2:

1. Non-secure EL1 System register accesses to the powerdown debug registers are trapped to EL2.
2. Non-secure EL1 System register accesses to the powerdown debug registers are not trapped to EL2.

Table D1-61 shows the register accesses that are trapped, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1. Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by MDCR_EL2.TDOSA</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR. Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by HDCR.TDOSA</td>
<td>Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.</td>
</tr>
</tbody>
</table>

---

**Note**

These registers are not accessible at EL0.

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDOSA is 1 other than for the purpose of a direct read.

*Trapping general System register accesses to debug registers to EL2*

MDCR_EL2.TDA traps Non-secure EL0 and EL1 System register accesses to those debug System registers that are not mentioned in either of the following:

- Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers on page D1-1935.
- Trapping System register accesses to powerdown debug registers to EL2.
This means that MDCR_EL2.TDA traps Non-secure EL0 and EL1 System register accesses to all debug System registers to EL2, except the following:

- Any access from:
  - AArch64 state to the MDRAR_EL1.
  - AArch32 state to the DBGDRAR or DBGDSAR.

MDCR_EL2.TDRA traps these accesses.

- Any access from:
  - AArch64 state to the OSLAR_EL1, OSLSR_EL1, OSDLR_EL1 or DBGPRCR_EL1.
  - AArch32 state to the DBGOSLSR, DBGOSLAR, OSDLR_EL1 or DBGPRCR.

MDCR_EL2.TDOSA traps these accesses.

When the PE is in Debug state, MDCR_EL2.TDA does not trap any access from:

- AArch32 state to DBGDTRRXint and DBGDTRTXint.
- AArch64 state to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.

When MDCR_EL2.TDA is:

0 Non-secure EL0 or EL1 System register accesses to the registers shown in Table D1-62 are not trapped to EL2.

Table D1-62 shows how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Table D1-62 Accesses trapped to EL2 when MDCR_EL2.TDA is 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traps from</td>
</tr>
<tr>
<td>------------</td>
</tr>
<tr>
<td>AArch64 state</td>
</tr>
<tr>
<td>AArch32 state</td>
</tr>
</tbody>
</table>

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDA is 1 other than for the purpose of a direct read.
Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers

CNTHCTL_EL2. {EL1PCEN, EL1PCTEN} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to EL2, as follows:
- CNTHCTL_EL2.EL1PCEN traps Non-secure EL0 and EL1 accesses to the physical timer registers.
- CNTHCTL_EL2.EL1PCTEN traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:
1 Non-secure EL0 and EL1 accesses are not trapped to EL2.
0 Non-secure EL0 and EL1 accesses are trapped to EL2.

Table D1-63 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>

<td>EL1PCTEN</td>
<td>CNTPCT</td>
<td></td>
</tr>
</tbody>
</table>

Table D1-63 Register accesses trapped to EL2 by CNTHCTL_EL2 trap controls

Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers

MDCR_EL2. {TPM, TPMCR} trap Non-secure EL0 and EL1 accesses to the Performance Monitors registers to EL2:

**MDCR_EL2.TPM**
1 Non-secure EL0 and EL1 accesses to the Performance Monitors registers are trapped to EL2.
0 Non-secure EL0 and EL1 accesses to the Performance Monitors registers are not trapped to EL2.

**MDCR_EL2.TPMCR**
1 Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers are trapped to EL2.
0 Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers are not trapped to EL2.

--- Note ---
EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

---
For:

- **MDCR_EL2.TPM == 1**, Table D1-64 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.
- **MDCR_EL2.TPMCR == 1**, Table D1-65 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.

### Table D1-64 Register accesses trapped to EL2 when MDCR_EL2.TPM is 1

<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

---

**Note**

MDCR_EL2.HPMN affects whether a counter can be accessed from Non-secure EL0 or EL1. See the register description of MDCR_EL2 for more information.

---

**Traps to EL2 of Non-secure EL1 accesses to the RAS error record registers**

HCR_EL2.TERR traps Non-secure EL1 accesses to the RAS ER* registers to EL2. For more information on the RAS ER* registers, see the *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.*
Enabling use of the Pointer authentication instructions, EL2 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

Each of the SCTLR_EL2.{EnDA, EnDB, EnIA, EnIB} fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL2 or EL2&0 translation regime. For more information see System register control of pointer authentication on page D4-2088.

Note

These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.

Trap to EL2 Non-secure EL1 accesses to Pointer authentication key registers

This control is implemented when ARMv8.3-PAuth is implemented.

HCR_EL2.API traps, to EL2, accesses to the Pointer authentication key registers from Non-secure EL1 to EL2. Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state. Table D1-66 shows the register accesses that are trapped and how the exceptions are reported in ESR_EL2:

Table D1-66 Register accesses trapped to EL2 when HCR_EL2.APK is 0

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>APDAKeyLo_EL1, APDAKeyHi_EL1, APDDBKeyLo_EL1, APDDBKeyHi_EL1, APIAKeyLo_EL1, APIAKeyHi_EL1, APIBKeyLo_EL1, APIBKeyHi_EL1</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>

For more information see System register control of pointer authentication on page D4-2088.

Trap to EL2 Non-secure EL0 accesses to Pointer authentication instructions

This control is implemented when ARMv8.3-PAuth is implemented.

HCR_EL2.API traps, to EL2, accesses to any of the Pointer authentication instructions for which pointer authentication is enabled, for instructions executed either:

- At Non-secure EL1.
- If the Effective value of HCR_EL2.{TGE, E2H} is not {1, 1}, at Non-secure EL0.

Because pointer authentication is supported only in AArch64 state, this control only traps from AArch64 state. Table D1-67 shows the instructions that might be trapped and how the exceptions are reported in ESR_EL2:

Table D1-67 Instructions that might be trapped to EL2 when HCR_EL2.API is 0

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Instructions that might be a trapped</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>AUTIASP, AUTIAZ, AUTIA1716, AUTIBSP, AUTIBZ, AUTIB1716, AUTIA, AUTIA, AUTIB, AUTDB, AUTIZA, AUTIZB, AUTIZB, PACIASP, PACIAZ, PACIA1716, PACIBSP, PACIBZ, PACIB1716, PACIA, PACIA, PACIB, PACIB, PACDB, PACIB, PACDB, PACDB, PACDBZ, PACDBZ, PACGA, XPACLRI, XPCAI, XPACD, RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETTA, ERETTB, LDRAA, LDRAB.</td>
<td>Trapped Pointer authentication instruction, using EC value 0x89.</td>
</tr>
</tbody>
</table>

a. An instruction is trapped only if Pointer authentication is enabled for that instruction.

For more information, including the description of when pointer authentication is enabled for an instruction, see System register control of pointer authentication on page D4-2088.
Disabling Address tagging for instruction accesses, EL2 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

When a TCR_EL2.TBI or TCR_EL2.{TBI0, TBI1} field enables the use of address tagging for the EL2 translation regime, the corresponding TCR_EL2.TBID or TCR_EL2.{TBID0, TBID1} field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information see Address tagging in AArch64 state on page D4-2084.

--- Note

These controls determine the scope of address tagging. They never cause an exception to be generated.

Traps to EL2 for Nested virtualization

These controls are implemented when ARMv8.3-NV is implemented.

HCR_EL2.NV traps the following to EL2 from Non-secure EL1:

- Some System register, System instruction, and Special-purpose register accesses that are UNDEFINED at Non-secure EL1 when ARMv8.3-NV is not implemented.
- Only accesses that are not UNDEFINED at EL2 are trapped.

--- Note

This means that, for a register that is RO at EL2, and UNDEFINED at Non-secure EL1 when ARMv8.3-NV is not implemented, when ARMv8.3-NV is implemented and this trap is enabled:
- Read accesses to the register from Non-secure EL1 are trapped to EL2.
- Write accesses to the register from Non-secure EL1 remain UNDEFINED.

- The execution of some instructions that are UNDEFINED at Non-secure EL1 when ARMv8.3-NV is not implemented.

Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state. Table D1-68 shows the registers and instructions that are trapped and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped register accesses or instructions</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>Any System or Special-purpose register named *_EL2, *_EL02, or *_EL12, except SP_EL2.</td>
<td>Trapped AArch64 MSR, MSR, or System instruction, using EC value 0x18.</td>
</tr>
<tr>
<td></td>
<td>SPSR_abt, SPSR_fiq, SPSR irq, SPSR甪nd, using an MSR or MSR instruction.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SP_EL1 using the dedicated MSR or MSR instruction.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>AT S1E2R, AT S1E2W, TLBI ALLE2, TLBI ALLE2IS, TLBI VAE2, TLBI VAE2IS, TLBI VALE2, TLBI VALE2IS</td>
<td></td>

<tr>
<td></td>
<td>AT S12E0R, AT S12E0W, AT S12E1R, AT S12E1W, TLBI ALLE1, TLBI ALLE1IS, TLBI IPAS2E1, TLBI IPAS2E1IS, TLBI IPAS2E1IS, TLBI VMALLS12E1, TLBI VMALLS12E1IS</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ERET, ERETTA, ERETAB.</td>
<td>Trapped ERET, ERETTA, or ERETAB instruction execution, using EC value 0x1A.</td>
</tr>
<tr>
<td></td>
<td>When EL3 is not implemented and HCR_EL2.TSC==1, SMC.</td>
<td>Trapped AArch64 SMC instruction, using EC value 0x17.</td>
</tr>
</tbody>
</table>

a. ERETTA and ERETAB are implemented when ARMv8.3-PAuth is implemented.
### Note

In addition, when the value of HCR_EL2.NV is 1, a read of CurrentEL returns the value 0b10 for bits[3:2].

**HCR_EL2.NV1 traps to EL2 from Non-secure EL1 accesses to some System registers and Special-purpose registers.** Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state. **Table D1-69** shows the registers that are trapped and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>VBAR_EL1, ELR_EL1, SPSR_EL1</td>
<td>Trapped AArch64 MSR, MR5, or System instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>

For more information see *Effect of HCR_EL2.{NV, NV1}* on page D4-2188.

### Trap to EL2 Non-secure EL1 accesses to AT S1E* instructions

This control is implemented when ARMv8.3-NV is implemented.

**HCR_EL2.AT traps to EL2 from Non-secure EL1 accesses to some Address translation instructions.** Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state. **Table D1-70** shows the registers that are trapped and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>AT S1E0R, AT S1E0W, AT S1E1R, AT S1E1W, AT S1E1RP, AT S1E1WP</td>
<td>Trapped AArch64 MSR, MR5, or System instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>

For more information see *Effect of HCR_EL2.{NV, NV1}* on page D4-2188.

### D1.15.4 EL3 configurable controls

These controls are in _EL3 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL3.M[4] indicates which Execution state the exception was taken from. **Table D1-71** shows the _EL3 System registers that contain these controls.

<table>

Also see the following for more general information about traps to EL3:
- Register access instructions on page D1-1911.
- Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1944.
Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32

If EL1 is using AArch32, all of the following are trapped to EL3:

- Secure EL1 reads and writes to any of the SCR, NSACR, MVBAR or SDCR.
- Any attempt at Secure EL1 to execute any of the following:
  - ATS12NSO** instructions.
  - MSR instructions that use the R13_mon banked register.
  - MRS or MSR instructions that access any of the SPSR_mon, R13_mon or R14_mon banked registers.

In addition, if EL1 is using AArch32:

- Secure EL1 write accesses to the CNTFRQ register are UNDEFINED. They are not trapped to EL3.
- Any attempt at Secure EL1 to change the PE mode to Monitor mode, by using a CPS or an MSR instruction, or by performing an exception return, is treated as an illegal change of the CPSR.M field. See Illegal changes to PSTATE.M on page G1-4618.

Table D1-74 shows the accesses that are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-74 Accesses trapped to EL3 from Secure EL1 using AArch32

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Trapped instructions, or trapped accesses</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure EL1 using AArch32</td>
<td>Reads and writes to any of the SCR, NSACR, MVBAR or SDCR</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td>ATS12NSO** instructions</td>
<td></td>
</tr>
<tr>
<td></td>
<td>MSR instructions that use the R13_mon banked register</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td></td>
<td>MRS or MSR instructions that access any of the SPSR_mon, R13_mon or R14_mon banked registers</td>
<td></td>
</tr>
</tbody>
</table>

Note

- Reads of the NSACR from either Non-secure EL1 using AArch32 or Non-secure EL2 using AArch32 return the value 0x00000C00. See Restricted access System registers on page G4-4973.
- These operations are not available at EL0.

Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions

SCR_EL3,TWE, TWI trap EL2, EL1, and EL0 execution of WFE and WFI instructions to EL3:

SCR_EL3,TWE

1  Any attempt to execute a WFE instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.

0  EL2, EL1, and EL0 execution of WFE instructions is not trapped.

SCR_EL3,TWI

1  Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.

0  EL2, EL1, and EL0 execution of WFI instructions is not trapped.

For EL0 and EL1, these traps apply to WFE and WFI execution in both Security states.
Table D1-75 shows how the exceptions are reported in ESR_EL3.

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR_EL3.TWE</td>
<td>Both Execution states</td>
<td>WFE</td>
<td>Trapped WFI or WFE instruction, using EC value 0x01</td>
</tr>
<tr>
<td>SCR_EL3.TWI</td>
<td></td>
<td>WFI</td>
<td></td>
</tr>
</tbody>
</table>

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait for Event mechanism and Send event* on page D1-1954.
- *Wait For Interrupt* on page D1-1957.

**Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers**

SCR_EL3.ST traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3:

1. Secure EL1 accesses to the Counter-timer Physical Secure timer registers are not trapped to EL3.
2. Secure EL1 accesses to the Counter-timer Physical Secure timer registers are trapped to EL3.

Note

Accesses to the Counter-timer Physical Secure timer registers are always enabled at EL3.

Table D1-76 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-76 Register accesses trapped to EL3 when SCR_EL3.ST is 0

<table>
<thead>
<tr>
<th>Traps from</th>

</tr>
<tr>
<td></td>
<td>CNTPS_CVAL_EL1</td>
<td></td>
</tr>
<tr>
<td>AArch32 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Note

These registers are not accessible at EL0.

**Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions**

SCR_EL3.HCE enables HVC instruction execution at EL1 and above:

1. HVC instruction execution is enabled at EL1 and above.
**D1 The AArch64 System Level Programmers’ Model**

**D1.15 Configurable instruction enables and disables, and trap controls**

0  

**HVC instructions are UNDEFINED at EL1, EL2, and EL3, and any resulting exception is taken from the current Exception level to the current Exception level.**

For EL1, this enable control applies to HVC instructions in Non-secure state only.

If EL2 is not implemented, this bit is RES0.

--- **Note** ---

HVC instructions are always UNDEFINED at EL0.

Table D1-77 shows how the exceptions are reported in ESR_ELx:

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled instruction</th>
<th>Syndrome reporting in ESR_ELx</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>HVC</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>AArch32 state</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Disabling EL3, EL2, and EL1 execution of SMC instructions**

**SCR_EL3.SMD** disables SMC instruction execution at EL1 and above:

1  

**SMC instructions are UNDEFINED at EL1 and above, and any resulting exception is taken from the current Exception level to the current Exception level.**

0  

**SMC instruction execution is enabled at EL1 and above.**

For EL1, this disable control applies to SMC instructions in both Security states.

--- **Note** ---

SMC instructions are always UNDEFINED at EL0.

Table D1-78 shows how the exceptions are reported in ESR_ELx:

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled Instruction</th>
<th>Syndrome reporting in ESR_ELx</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>SMC</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>AArch32 state</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

--- **Note** ---

If **HCR_EL2.TSC** or **HCR.TSC** traps attempted EL1 execution of SMC instructions to EL2, that trap has priority over this disable.

**Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR**

**CPTR_EL3.TCPAC** traps all of the following to EL3:

- EL2 accesses to the CPTR_EL2 or HCPR.
- EL2 and EL1 accesses to the CPACR_EL1 or CPACR.
When **CPTR_EL3.TCPAC** is:

1. EL2 accesses to the **CPTR_EL2** or **HCPTR**, and EL2 and EL1 accesses to the **CPACR_EL1** or **CPACR**, are trapped to EL3.

0. EL2 accesses to the **CPTR_EL2** or **HCPTR**, and EL2 and EL1 accesses to the **CPACR_EL1** or **CPACR**, are not trapped to EL3.

For EL1, this trap control applies to accesses from both Security states.

Table D1-79 shows how the exceptions are reported in **ESR_EL3**.

### Table D1-79 Register accesses trapped to EL3 when **CPTR_EL3.TCPAC** is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in <strong>ESR_EL3</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>CPTR_EL2, CPACR_EL1</td>
<td>Trapped AArch64 MSR, MSR, or system instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>HCPTR, CPACR</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**Traps to EL3 of all System register accesses to the trace registers**

**CPTR_EL3.TTA** traps System register accesses to the trace registers, from all Exception levels, to EL3:

1. All System register accesses to the trace registers are trapped to EL3.

0. System register accesses to the trace registers are not trapped to EL3.

---

**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a **CPTR_EL3.TTA** Trap exception.

- EL3 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see **Register access instructions on page D1-1911**.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-80 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in **ESR_EL3**.

### Table D1-80 Register accesses trapped to EL3 when **CPTR_EL3.TTA** is 1

<table>

| AArch32 state | All implemented trace registers | For accesses using:  
  - MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.  
  - MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0xC |
Traps to EL3 of all accesses to the SIMD and floating-point registers

CPTR_EL3.TFP traps all accesses to SIMD and floating-point registers, from all Exception levels, to EL3:

<table>
<thead>
<tr>
<th>Control</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Any attempt at any Exception level to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL3.</td>
</tr>
<tr>
<td>0</td>
<td>Execution of instructions that access the SIMD or floating-point registers is not trapped to EL3.</td>
</tr>
</tbody>
</table>

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-81 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-81 Register accesses trapped to EL3 when CPTR_EL3.TFP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>FPCR, FPSR, FPEXC32_EL2, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See The SIMD and floating-point registers, V0-V31 on page D1-1860.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-4699.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07</td>
</tr>
</tbody>
</table>

Note

- FPEXC32_EL2 is not accessible from EL0 using AArch64.
- FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.

Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers

MDCR_EL3.\{TDOSA, TDA\} trap EL2, EL1, and EL0 System register accesses to the debug registers to EL3, from both Security states.

Note

EL3 does not provide traps on debug register accesses through the Memory-mapped or External debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL3, no side-effects occur before the exception is taken to EL3. See Register access instructions on page D1-1911.

Table D1-82 shows the subsections that list the accesses trapped.

Table D1-82 Traps of EL2, EL1, and EL0 accesses to debug registers

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Subsection</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDCR_EL3.TDOSA</td>
<td>Trapping System register accesses to powerdown debug registers to EL3 on page D1-1949</td>

<tr>
<td>MDCR_EL3.TDA</td>
<td>Trapping general System register accesses to debug registers to EL3 on page D1-1949</td>
</tr>
</tbody>
</table>
Trapping System register accesses to powerdown debug registers to EL3

MDCR_EL3.TDOSA traps EL2 and EL1 accesses to the powerdown debug registers to EL3:

1  EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3.
0  EL2 and EL1 System register accesses to the powerdown debug registers are not trapped to EL3.

For EL1, this trap control applies to accesses from both Security states.

Table D1-83 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL3.

Table D1-83 Register accesses trapped to EL3 when MDCR_EL3.TDOSA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1. Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by MDCR_EL3.TDOSA.</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR.</td>
</tr>
</tbody>
</table>

Syndrome reporting in ESR_EL3

Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.

For accesses using:
- MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.
- MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.

Note

These registers are not accessible at EL0.

Trapping general System register accesses to debug registers to EL3

MDCR_EL3.TDA traps EL2, EL1, and EL0 System register accesses to the debug System registers that are not mentioned in Trapping System register accesses to powerdown debug registers to EL3.

This means that MDCR_EL3.TDA traps EL2, EL1, and EL0 System register accesses to all debug System registers, except the following:
- Accesses from AArch64 state to the OSLAR_EL1, OSLSR_EL1, OSDLR_EL1 or DBGPRCR_EL1.
- Accesses from AArch32 state to the DBGOSLSR, DBGOSLAR, OSDLR_EL1 or DBGPRCR.

When MDCR_EL3.TDA is:

1  EL2, EL1, and EL0 System register accesses to any of the registers shown in Table D1-84 on page D1-1950 are trapped to EL3.
0  EL2, EL1, and EL0 System register accesses to the registers shown in Table D1-84 on page D1-1950 are not trapped to EL3.

For EL0 and EL1, this trap control applies to accesses from both Security states.

When the PE is in Debug state, MDCR_EL3.TDA does not trap any access from:
- AArch32 state to DBGDTRRXint and DBGDTRTXint.
- AArch64 state to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.
Table D1-84 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL3.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>Accesses to the MDCR_EL2, MDRAR_EL1, MDCCSR_EL0, MDCCINT_EL1, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, OSDTRRX_EL1, OSECCR_EL1, OSECCR_EL0, DBGBCR&lt;n&gt;_EL1, DBGWVR&lt;n&gt;_EL1, DBGWCR&lt;n&gt;_EL1, DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, DBGAUTHSTATUS_EL1, and DBGVCR32_EL2.</td>
<td>Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>
| AArch32 state | Accesses to the HDCR, DBGDRAR, DBGDSAR, DBGDIDR, DBGDSCRint, DBGDCINT, DBGDTRRXint, DBGDTRTXint, DBGWFAR, DBGVCR, DBGDSCRext, DBGDTRRXext, DBGDTRTXext, DBGBCR<n>, DBGBXVR<n>, DBGWCR<n>, DBGWVR<n>, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, and DBGOSECCR. | For accesses using:  
- MCR or MRC instructions, trapped MCR or MRC access (coproc == 0b1110), using EC value 0x05.  
- MRRC instructions, trapped MCR or MRC access (coproc == 0b1111), using EC value 0x0C.  
Accesses to the SDER. Trapped MCR or MRC access (coproc == 0b1111), using EC value 0x03.  
STC accesses to DBGDTRRXint. LDC or STC, trapped LDC or STC access, using EC value 0x06. |

Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers

MDCR_EL3.TPM traps EL2, EL1, and EL0 accesses to the Performance Monitors registers to EL3:

- **1** EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are trapped to EL3.
- **0** EL2, EL1, and EL0 System register accesses to Performance Monitors registers are not trapped to EL3.

For EL0 and EL1, this trap control applies to accesses from both Security states.
Table D1-85 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL3.

### Table D1-85 Register accesses trapped to EL3 when MDCR_EL3.TPM is 1

</table>
| AArch32 state | PMCR, PMCNTENSET, PMCNTENCEL, PMOVSR, PMSWINC, PMSEL, PMCEID0, PMCEID1, PMCCNTR, PMXEVTPYER, PMXEVCNTR, PMUSERLEN, PMINTENSET, PMINTENCLR, PMOVSET, PMEVCNTR<α>, PMEVTYPER<α>, PMCCFILTR. | For accesses using: 
|              | • MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |
|              | • MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 |

### Traps to EL3 of EL2 and EL1 accesses to RAS error record registers

**SCR_EL3.TERR** traps EL2 and EL1 accesses to the RAS ER* registers to EL3. For more information on the RAS ER* registers, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

For EL2 and EL1, this trap control applies to accesses from both Security states.

### Enabling use of the Pointer authentication instructions, EL3 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

Each of the SCTLR_EL3.{EnDA, EnDB, EnIA, EnIB} fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL3 translation regime. For more information see System register control of pointer authentication on page D4-2088.

--- **Note** ---

These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.
### Trap to EL3 accesses to Pointer authentication key registers

This control is implemented when ARMv8.3-PAuth is implemented.

**SCR_EL3/API** traps, to EL3, accesses to the Pointer authentication key registers from EL2 or from Secure or Non-secure EL1. Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state. Table D1-86 shows the register accesses that are trapped and how the exceptions are reported in ESR_EL3:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>APDAKeyLo_EL1, APDAKeyHi_EL1, APDBKeyLo_EL1,</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18.</td>
</tr>
<tr>
<td></td>
<td>APDBKeyHi_EL1, APGAKeyLo_EL1, APGAKeyHi_EL1,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>APIAKeyLo_EL1, APIAKeyHi_EL1, APIBKeyLo_EL1,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>APIBKeyHi_EL1</td>
<td></td>
</tr>
</tbody>
</table>

For more information see [System register control of pointer authentication on page D4-2088](#).

### Trap to EL3 accesses to Pointer authentication instructions

This control is implemented when ARMv8.3-PAuth is implemented.

**SCR_EL3/API** traps, to EL3, accesses to any of the Pointer authentication instructions for which pointer authentication is enabled, for instructions executed at an exception level lower than EL3, in either Security state.

Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state. Table D1-87 shows the instructions that might be trapped and how the exceptions are reported in ESR_EL3:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Instructions that might be trapped</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>AUTIASP, AUTIAZ, AUTIA1716, AUTIB5P, AUTIBZ, AUTIB1716, AUTIA, AUTDA, AUTIB, AUTDB, AUTIZA, AUTIZB, AUTIADP, PACIA5P, PACIAZ, PACIA1716, PACIB5P, PACIBZ, PACIB1716, PACIA, PACDA, PACIB, PACDB, PACIAXA, PACIZA, PACIZB, PACIZB, PACGA, XPAACLRI, XPACI, XPACD, RETAA, RETAB, BAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETA, ERETAB, LDRAA, LDRAEB.</td>
<td>Trapped Pointer authentication instruction, using EC value 0x09.</td>
</tr>
</tbody>
</table>

a. An instruction is trapped only if Pointer authentication is enabled for that instruction.

For more information, including the description of when pointer authentication is enabled for an instruction, see [System register control of pointer authentication on page D4-2088](#).

### Disabling Address tagging for instruction accesses, EL3 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

When the TCR_EL3.TBI field enables the use of address tagging for the EL3 translation regime, the TCR_EL3.TBID field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information see [Address tagging in AArch64 state on page D4-2084](#).

---

**Note**

This control determines the scope of address tagging. It never causes an exception to be generated.
D1.16 System calls

A system call is generated by the execution of an SVC, HVC, or SMC instruction:

- By default, the execution of an SVC instruction generates a Supervisor Call, a synchronous exception that targets EL1. This provides a mechanism for software executing at EL0 to make a call to an operating system or other software executing at EL1.

- In an implementation that includes EL2, the execution of an HVC instruction generates a Hypervisor Call, a synchronous exception that targets EL2 by default.

  The HVC instruction is UNDEFINED:
  - At EL0.
  - At EL1 in Secure state.

  Note
  Software executing at EL0 cannot directly generate a Hypervisor Call.

- In an implementation that includes EL3, by default the execution of an SMC instruction generates a Secure Monitor Call, a synchronous exception that targets EL3.

  The SMC instruction is UNDEFINED at EL0, meaning software executing at EL0 cannot directly generate a Secure Monitor Call.

The default behavior applies when the instruction is not UNDEFINED and both of the following are true:

- The instruction is executed at an Exception level that is the same as or lower than the target Exception level.
- The instruction is not trapped to a different Exception level.

If an SVC or HVC instruction is executed at an Exception level that is higher than the target Exception then it generates a synchronous exception that is taken to the current Exception level.

EL2 and EL3 can disable Hypervisor Call exceptions, see:

- Disabling Non-secure state execution of HVC instructions on page D1-1923.
- Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions on page D1-1945.

EL2 can trap use of the SMC instruction, see Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1927.

EL3 can disable Secure Monitor Call exceptions, see Disabling EL3, EL2, and EL1 execution of SMC instructions on page D1-1946.

D1.16.1 Pseudocode description of system calls

The AArch64.CallSupervisor() pseudocode function performs an SVC call in AArch64 state.

The AArch64.CallHypervisor() pseudocode function performs an HVC call in AArch64 state.

The AArch64.CallSecureMonitor() pseudocode function performs an SMC call in AArch64 state.

The AArch64.CallSupervisor(), AArch64.CallHypervisor(), and AArch64.CallSecureMonitor() functions are described in Chapter J1 ARMv8 Pseudocode.
D1.17   Mechanisms for entering a low-power state

The ARM architecture provides mechanisms that software can use to indicate that the PE can enter a low-power state, if it supports that state. The following sections describe those mechanisms:

- Wait for Event mechanism and Send event.
- Wait For Interrupt on page D1-1957.

D1.17.1   Wait for Event mechanism and Send event

A PE can use the Wait for Event (WFE) mechanism to enter a low-power state, depending on the value of the Event Register for that PE. To enter the low-power state, the PE executes a Wait For Event instruction, WFE, and if the Event Register is clear, the PE can enter the low-power state.

If the PE does enter the low-power state, it remains in that low-power state until it receives a WFE wake-up event.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFE instruction must not cause a loss of memory coherency.

WFE mechanism behavior depends on the interaction of all of the following, that are described in the subsections that follow:

- The Event Register for the PE. See subsection The Event Register on page D1-1955.
- WFE wake-up events. See subsection WFE wake-up events in AArch64 state on page D1-1956
- The Send Event instructions, SEV and SEVL that can cause WFE wake-up events. See subsection The Send Event instructions on page D1-1956.

Note

Because the Wait for Event mechanism is associated with suspending execution on a PE for the purpose of power saving, ARM recommends that the Event Register is set only infrequently. However, software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

Example D1-2 describes how a spinlock implementation might use the WFE mechanism to save energy.

Example D1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device, it might need to add data received from the device to a queue. If another PE is removing data from the same queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the second PE has released the lock. The first PE cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in Synchronization and semaphores on page B2-128.
- If the PE obtains the lock it performs its memory operation and then releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. When the lock becomes available, the PE again attempts to obtain it.
A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multiprocessor system the execution of spin-locks by multiple waiting PEs can degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock:

- A PE that fails to obtain a lock executes a WFE instruction to request entry to a low-power state, at the time when the Exclusives monitor is set holding the address of the location holding the lock.
- When a PE releases a lock, the write to the lock location causes the Exclusives monitor of any PE monitoring the lock location to be cleared. This clearing of the Exclusives monitors generates a WFE wake-up event for each of those PEs. Then, these PEs can attempt to obtain the lock again.

For large systems, more advanced locking systems, such as ticket locks, can avoid unfairness caused by having multiple PEs simultaneously reading the lock. In such systems, the WFE mechanism can be used in a similar way to monitor the next ticket value.

The Event Register

The Event Register is a single bit register for each PE. When set, an Event Register indicates that an event has occurred since the register was last cleared, that might require some action by the PE. Therefore, when the Event Register is set, the PE must not suspend operation on executing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by any of the following:

- A Send Event instruction, SEV, executed by any PE in the system.
- A Send Event Local instruction, SEVL, executed by the PE.
- An exception return.
- The clearing of the global monitor for the PE.
- An event from a Generic Timer event stream, see Event streams on page D8-2328.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

The Event Register is cleared only by a Wait For Event instruction.

Note

Software cannot read or write the value of the Event Register directly.

The Wait For Event instruction

The action of the Wait For Event instruction, WFE, depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately.
- If the Event Register is clear the PE can suspend execution and enter a low-power state. It remains in that state until the PE detects a WFE wake-up event, or earlier if the implementation chooses, or until a reset. When the PE detects a WFE wake-up event, or earlier if chosen, the WFE instruction completes. If the wake-up event sets the Event Register, it is IMPLEMENTATION DEFINED whether on restarting execution, the Event Register is cleared.

The WFE instruction is available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1913.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1931.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1944.
WFE wake-up events in AArch64 state

The following are WFE wake-up events:

- The execution of an SEV instruction on any PE in the multiprocessor system.

- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by EDSCR.INTdis and:
  - Is marked as A in the tables in Asynchronous exception masking on page D1-1905, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
  - Is marked as B in the tables in Asynchronous exception masking on page D1-1905, if the value of the corresponding PSTATE.{A, I, F} mask bit is 0.

- In Non-secure EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by EDSCR.INTdis and is marked as B in Table D1-19 on page D1-1908 in Virtual interrupts on page D1-1907, if the value of the corresponding PSTATE.{A, I, F} mask bit is 0.

- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed see Halting allowed and halting prohibited on page H2-5697.
  
  See also External Debug Request debug event on page H3-5752.

- An event sent by the timer event stream for the PE. See Event streams on page D8-2328.

- An event caused by the clearing of the global monitor for the PE.

- An event sent by some IMPLEMENTATION DEFINED mechanism.

Not all of these wake-up events set the Event Register.

—— Note ————

The disabling of interrupts, and WFE wake-up events, by EDSCR.INTdis is possible only when external debug is enabled.

—— The Send Event instructions ———

The Send Event instructions are:

**SEV, Send Event**  
This causes an event to be signaled to all PEs in the multiprocessor system.

**SEVL, Send Event Local**  
This must set the local Event Register.

—— Note ————

It might signal an event to other PEs by some IMPLEMENTATION DEFINED mechanism, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before any SEV instruction.
### Note

A DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See *Data Synchronization Barrier (DSB)* on page B2-100.

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

The receipt of a signaled SEV or SEVL event by a PE sets the Event Register on that PE.

The SEV and SEVL instructions are available at all Exception levels.

### Pseudocode description of the Wait For Event mechanism

This section identifies pseudocode functions that describe the behavior of the Wait For Event mechanism.

The `ClearEventRegister()` pseudocode function clears the Event Register of the current PE.

The `IsEventRegisterSet()` pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The `WaitForEvent()` pseudocode function optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes `ClearEventRegister()` to be called.

The `SendEvent()` pseudocode function sets the Event Register of every PE in the multiprocessor system.

The `SendEventLocal()` pseudocode function sets the event register for the local PE.

---

### D1.17.2 Wait For Interrupt

Software can use the *Wait for Interrupt (WFI)* instruction to cause the PE to enter a low-power state. The PE then remains in that low-power state until it receives a *WFI wake-up event*, or until some other IMPLEMENTATION DEFINED reason causes it to leave the low-power state. The architecture permits a PE to leave the low-power state for any reason, but requires that it must leave the low-power state on receipt of any architected WFI wake-up event.

---

Because the architecture permits a PE to leave the low-power state for any reason, it is permissible for a PE to treat WFI as a NOP, but this is not recommended for lowest power operation.

---

When the PE leaves a low-power state that was entered as a result of a WFI instruction, that WFI instruction completes.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFI instruction must not cause a loss of memory coherency.

Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1913.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1931.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1944.

### WFI wake-up events

The following are *WFI wake-up events*:

- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as A as B in the tables in *Asynchronous exception masking* on page D1-1905, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
• In Non-secure EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as B in Table D1-19 on page D1-1908 in Virtual interrupts on page D1-1907, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.

• An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed see Halting allowed and halting prohibited on page H2-5697.

See also External Debug Request debug event on page H3-5752.

• An event sent by some IMPLEMENTATION DEFINED mechanism.

--- Note ---

• WFI wake-up events are never disabled by EDSCR.INTdis, and are never masked by the PSTATE.{A, I, F} mask bits. If wake-up is invoked by an interrupt that is disabled or masked the interrupt is not taken.

• Because debug events are WFI wake-up events, ARM recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.

• Some implementations of the WFI mechanism drain down any pending memory activity before suspending execution. This increases power saving, by increasing the area over which clocks can be stopped. The architecture does not require this operation, therefore software must not rely on the WFI mechanism operating in this way.

---

Using WFI to indicate an idle state on bus interfaces

Software can use the WFI mechanism to force quiescence on a PE, and, combined with preventing any possible WFI wakeup events, this can be used to complete an entry into a powerdown state.

Because mechanisms for entering powerdown states are inherently IMPLEMENTATION DEFINED, whether an implementation uses the WFI mechanism is IMPLEMENTATION DEFINED. If it does, the WFI instruction forces the suspension of execution, and of all associated bus activity.

The control logic that does this also tracks the activity on the bus interfaces of the PE, so that when the PE has completed all current operations and any associated bus activity has completed, it can signal to an external power controller that there is no ongoing bus activity.

However, the PE must continue to process memory-mapped and external debug interface accesses to debug registers when in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the OS Double Lock control, OSDLR_EL1.DLK, is 1, the PE must not signal this idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see Debug behavior when the OS Double Lock is locked on page H6-5807.

--- Note ---

In a PE that implements separate core and debug power domains, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see Power domains and debug on page H6-5799.

---

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

Pseudocode description of Wait For Interrupt

The WaitForInterrupt() pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.
D1.18 **Self-hosted debug**

The ARMv8-A architecture supports both of the following:

**Self-hosted debug**

The PE itself hosts a debugger. The debugger programs the PE to generate debug exceptions. Debug exceptions are accommodated in the ARMv8-A Exception model.

**External debug**

The PE is controlled by an external debugger. The debugger programs the PE to generate Debug events, that cause the PE to enter Debug state. In Debug state, the PE is halted.

This section describes self-hosted debug. It includes:

- Debug exceptions.
- The PSTATE debug mask bit, D.

For external debug, see part E.

D1.18.1 **Debug exceptions**

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

The possible debug exceptions are:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

Chapter D2 *AArch64 Self-hosted Debug* describes these in detail for AArch64.

For the PE to generate a debug exception requires that:

- The debug exception is enabled. The debug exception enable controls on page D2-1984 gives the controls for the different debug exceptions.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state on page D2-1987.

Debug exceptions are synchronous exceptions, and are accommodated in the ARMv8 Exception model.

---

**Note**

Breakpoints and Watchpoints can cause entry to Debug state instead of causing debug exceptions. See Chapter H1 *About External Debug*.

---

D1.18.2 **The PSTATE debug mask bit, D**

As with all other exceptions, when a debug exception is taken, software must take care to avoid generating another instance of an exception within the exception handler, to avoid recursive entry into the exception handler and loss of return state.

To help avoid this, the ARMv8 architecture provides a debug exception mask bit, PSTATE.D, that can mask Watchpoint, Breakpoint, and Software Step exceptions when the target Exception level is the current Exception level.
PSTATE.D is set to 1 on taking an exception. This means that while handling an exception in AArch64 state, Watchpoint, Breakpoint, and Software Step exceptions are masked. This prevents recursive entry at the Exception level that debug exceptions are targeted to.

When execution is in AArch64 state, debug exceptions are also masked implicitly when the target Exception level is lower than the current Exception level.

When the target Exception level is higher than the current Exception level, debug exceptions cannot be masked by PSTATE.D.

Because debug exceptions are synchronous, the architecture requires that debug exceptions are not generated when PSTATE.D is 1. By preventing debug exception generation, debug exceptions cannot be taken at a subsequent time when the Process state D mask bit is cleared to 0.

**Note**

This differs from the behavior for interrupts, where the PSTATE.{A, I, F} mask has the effect of preventing the interrupt from being taken, but instead the interrupt remains pending.
D1.19 The Performance Monitors Extension

The System registers provide access to a Performance Monitors Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE. The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of 32-bit event counters. Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:
  - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
  - Implementation-specific events. The PMU specification reserves event numbers for implementation-specific events. See Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events.

For more information, see Chapter D5 The Performance Monitors Extension.
D1.20 Interprocessing

*Interprocessing* is the term used to describe moving between the AArch64 and AArch32 Execution states.

The Execution state can change only on a change of Exception level. This means that the Execution state can change only on taking an exception to a higher Exception level, or returning from an exception to a lower Exception level.

On taking an exception to a higher Exception level, the Execution state either:
- Remains unchanged.
- Changes from AArch32 state to AArch64 state.

On returning from an exception to a lower Exception level, the Execution state either:
- Remains unchanged.
- Changes from AArch64 state to AArch32 state.

**Note**

If, on taking or returning from an exception, the Exception level remains the same, the Execution state cannot change.

For the description of:
- Exception entry to an Exception level using AArch64, see *Exception entry* on page D1-1874.
- Exception return from an Exception level using AArch64 state, see *Exception return* on page D1-1883.
- Exception return to AArch32 state, see *Exception return to an Exception level using AArch32* on page G1-4645.

**Note**

The description in *Handling exceptions that are taken to an Exception level using AArch32* on page G1-4622 is outside the scope of interprocessing, because such exceptions must have been taken from an Exception level that is using AArch32, and therefore there is no change of Execution state.

The following sections describe the behavior associated with interprocessing.
- *Register mappings between AArch32 state and AArch64 state*.
- *State of the general-purpose registers on taking an exception to AArch64 state* on page D1-1971.
- *SPSR, ELR, and AArch64 SP relationships on changing Execution state* on page D1-1972.

D1.20.1 Register mappings between AArch32 state and AArch64 state

This section defines the architectural mappings between AArch32 state registers and AArch64 state registers.

The mappings describe:
- For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
- For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

The general model is:
- The AArch32 register contents are situated in the bottom 32 bits of the AArch64 registers.
- In AArch32 state, the upper 32 bits of AArch64 registers are inaccessible and are ignored.

**Note**

System software that executes in AArch64 state, such as an OS or Hypervisor, can use these mappings for context save and restore, or to interpret and modify the AArch32 registers of an application or virtual machine.
For more information see the following subsections:

- Mapping of the general-purpose registers between the Execution states.
- Mapping of the SIMD and floating-point registers between the Execution states on page D1-1964.

Mapping of the general-purpose registers between the Execution states

Table D1-88 shows how each of the AArch32 general-purpose registers, R0-R12, SP, and LR, including the banked copies of these registers, maps to an AArch64 general-purpose register. A register in the AArch64 register column of the table provides the AArch64 view of the corresponding register in the AArch32 register column.

Note

For some exceptions, the exception syndrome given in the ESR_ELx identifies one or more register numbers from the issued instruction that generated the exception. Where the exception is taken from an Exception level using AArch32 these register numbers give the AArch64 view of the register. For example, if an exception is taken from AArch32 Abort mode, and the faulting instruction specified R14, the ESR_ELx.ISS field would report this using the EC value $0b10100$, because register X20 provides the AArch64 view of LR_abt. which is the copy of R14 used in Abort mode.

The AArch64 registers V16-V31 are not accessible from AArch32 state.

The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state:

- In AArch64 state, there are:
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.
A smaller register occupies the least-significant bytes of the corresponding larger register. For example, S5 is the least-significant word of D5 and V5. Figure D1-3 shows this mapping.

**Figure D1-3 AArch64 state SIMD and floating-point register mappings**

- In AArch32 state, there are:
  - 16 128-bit Q registers, Q0-Q15.
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.

Smaller registers are packed into larger registers. Figure D1-4 shows this mapping.

**Figure D1-4 AArch32 state SIMD and floating-point register mappings**

<table>

<td>D(2n+1)</td>
<td>D(2n)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In AArch32 state:

- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15. For example, D16 and D17 pack into Q8.

**Note**

A consequence of this mapping is that if software executing in AArch64 state interprets D or S registers from AArch32 state, it must unpack the D or S registers from the V registers before it uses them.

---

**Mapping of the System registers between the Execution states**

ARMv8 architecturally defines the relationship between the AArch64 System registers and the AArch32 System registers, to allow supervisory code such as a hypervisor, that is executing in AArch64 state, to save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

Any modifications made to AArch32 System registers affects only those parts of those AArch64 registers that are mapped to the AArch32 System registers. Bits[63:32] of AArch64 registers, where they are not mapped to AArch32 registers, are unchanged by AArch32 state execution.

**Note**

This model is different to the model for the general-purpose registers described in *Mapping of the general-purpose registers between the Execution states* on page D1-1963. In this model, there are several cases where two AArch32 System registers are packed into a single AArch64 System register.

When EL3 is implemented and is using AArch32, some System registers are banked between the two Security states. When a register is banked in this way, there is an instance of the register in Secure state, and another instance of the register in Non-secure state. In *Table D1-90 on page D1-1966* these banked registers are identified by footnote. This banking is not supported when EL3 is using AArch64 or if EL3 is not implemented. This means that when EL3 is implemented and is using AArch64, exactly the same registers are accessed in the following states:

- Secure EL1 with EL1 using AArch32.
- Non-secure EL1 with EL1 using AArch32.
This means that, architecturally, it is not possible to determine whether an AArch64 register is mapped onto the Secure instance of the corresponding AArch32 register, or onto the Non-secure instance of that register. When EL3 is using AArch64, the interrupt asserted by the AArch64 CNTP_* timer is the same interrupt as is asserted by the Non-secure AArch32 CNTP_* timer when EL3 is using AArch32.

Note
Although the architecture does not require this, because it is not architecturally visible, ARM expects that implementations will map many of the AArch64 registers for use by EL3 to the Secure instances of the banked AArch32 registers, and will map many of the AArch64 registers for use by EL1 to the Non-secure instances of the banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this is not possible for the following registers:

- **IFAR**  
  This is because when EL3 is using AArch32, HIFAR is an alias of the Secure IFAR.

- **DFAR**  
  This is because when EL3 is using AArch32, HDFAR is an alias of the Secure DFAR.

Table D1-90 shows the mappings between the writable AArch64 System registers and the AArch32 System registers.

a. AArch32 registers that are banked if EL3 is using AArch32.
b. These registers have overlapping register content. One or more bits of one register appear in the other register.
There are a small number of AArch32 System registers that are not mapped to any AArch64 System registers. The AArch64 registers listed in Table D1-91 can be used to access these from a higher Exception level that is using AArch64. The registers shown in the table are UNDEFINED if EL1 cannot use AArch32.

## D1.20.2 State of the general-purpose registers on taking an exception to AArch64 state

When an exception is taken from AArch32 state to AArch64 state, the state of a general-purpose register depends on whether, immediately before the exception, the register was accessible from AArch32 state, as follows:

### If the general-purpose register was accessible from AArch32 state

The upper 32 bits either become zero, or hold the value that the same architectural register held before any AArch32 execution. The choice between these two options is IMPLEMENTATION DEFINED, and might vary dynamically within an implementation. Correspondingly, software must regard the value as being a CONSTRAINED UNPREDICTABLE choice between these two values.

This behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32. That is, this behavior applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

Which general-purpose registers have their upper 32 bits affected in this way depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-93 shows which general-purpose registers can have their upper 32 bits set to zero.

### Table D1-93 General-purpose registers that can have their upper 32 bits set to zero on taking an exception to AArch64 state from AArch32 state

<table>
<thead>
<tr>
<th>SCR_EL3.RW</th>
<th>HCR_EL2.RW or HCR.RW</th>

<td>1</td>
<td>X0-X14</td>
<td>X0-X14</td>
<td>X0-X14</td>
</tr>
</tbody>
</table>

a. HCR.RW is a notional bit that is RES0.
b. The RW bit values are not valid for the targeted Exception level.
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

### Note

If EL2 is not implemented, or the SCR_EL3.NS or SCR.NS bit prevents its use, then as described in The effects of supporting fewer than four Exception levels on page D1-1976, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.

If the general-purpose register was not accessible from AArch32 state

The general rule is that the register retains the state it had before any AArch32 execution.

There is one exception to this rule, that is when taking an exception to EL3 using AArch64 when either EL2 is not implemented or EL1 is in Secure state. In these cases, the X15 register must be treated as if it is accessible when the value of SCR_EL3.RW is 0, and therefore the upper bits of X15 might either be set to zero or retain their previous value.
Which general-purpose registers retain their state depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-94 shows which general-purpose registers can retain their state.

Table D1-94 General-purpose registers that can retain their state on taking an exception to AArch64 from AArch32

</tr>
</tbody>
</table>

On exception entry to EL3 using AArch64 state from an Exception level using AArch32 state, when EL2 has been using AArch32 state, the upper 32-bits of ELR_EL2 are either set to zero or they retain the value before the AArch32 state execution. The implementation determines the choice between these two options, and the choice might vary dynamically within an implementation. Therefore, software must regard the upper 32-bits as being UNKNOWN.

On exception entry to an Exception level using AArch64 state from an Exception level using AArch32 state, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during execution in AArch32 state at that Exception level, retain the state that they had before the execution in AArch32 state.
The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state when there is execution at EL1 with EL1 using AArch64 state:

- SPSR_abt.
- SPSR_und.
- SPSR_irq.
- SPSR_fiq.

**Note**

- These registers are accessible during execution in AArch64 state at Exception levels higher than EL1, for context switching.
- If EL1 does not support execution in AArch32 state then these registers are RES0.

On exception entry to an Exception level using AArch64 from an Exception level using AArch32, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during AArch32 execution at that Exception level retain the state that they had before AArch32 execution. This applies to the following registers:

- SP_EL0.
- SP_EL1.
- SP_EL2.
- ELR_EL1.
**D1.21 The effect of implementation choices on the programmers’ model**

Three of the implementation choices in ARMv8 are:

- The number of Exception levels implemented.
- Which Exception levels support AArch32 and which Exception levels support AArch64.
- Whether SIMD and floating-point support is implemented.

The following subsections give more information about how these choices affect the programmers’ model:

- Implication of Exception levels implemented.
- Support for Exception levels and Execution states on page D1-1975.
- Implementations not including Advanced SIMD and floating-point instructions on page D1-1976.
- The effects of supporting fewer than four Exception levels on page D1-1976.

**D1.21.1 Implication of Exception levels implemented**

All implementations must include EL0 and EL1.

EL2 and EL3 are optional. The architecture permits all combinations of EL2 and EL3.

See also Implementations not including Advanced SIMD and floating-point instructions on page D1-1976 and The effects of supporting fewer than four Exception levels on page D1-1976.

For an implementation that includes all of the Exception levels Figure D1-5 shows the implemented Exception levels and the possible Execution states at lower Exception levels when EL3 is using AArch64. Figure D1-5 applies regardless of whether EL3 also supports use of AArch32.

![Figure D1-5 ARMv8-A security model when EL3 is using AArch64](image)

† AArch64 permitted only if EL1 is using AArch64
‡ AArch64 permitted only if EL2 is using AArch64

---

**Figure D1-5 ARMv8-A security model when EL3 is using AArch64**
The possible combinations of Exception levels are as follows:

- EL0, EL1, and EL2. The implementation supports only Non-secure state.

- EL0, EL1, and EL3. The implementation does not support Virtualization. The Exception levels and Execution states depend on whether EL3 is using AArch64 state or AArch32 state, as follows:
  - If EL3 is using AArch64, the Exception levels and Execution states are as shown in Figure D1-5 on page D1-1974 with EL2 removed and no Non-secure state virtualization of EL1 and EL0.
  - If EL3 is using AArch32, the Exception levels and Execution states are as shown in Figure G1-1 on page G1-4598 with EL2 removed and no Non-secure state virtualization of EL1 and EL0.

- EL0 and EL1 only. The implementation supports only a single Security state. This might be either Secure state or Non-secure state, see Behavior when only EL1 and EL0 are implemented on page D1-1978.

- EL0, EL1, EL2, and EL3, as described in this section.

For more information, see The effects of supporting fewer than four Exception levels on page D1-1976.

## D1.21.2 Support for Exception levels and Execution states

Subject to the interprocessing rules defined in Interprocessing on page D1-1962, an implementation of the ARM architecture could support:

- AArch64 state only.
- AArch64 and AArch32 states.
- AArch32 state only.

This means the ARMv8-A architecture can, potentially, support implementations with very large number of combinations of Execution state and Exception level. ARM intends to license only a subset of the possible combinations. Table D1-96 shows the combinations of Exception levels and Execution states that are currently licensed.

D1.21.3 Implementations not including Advanced SIMD and floating-point instructions

In general, ARMv8-A requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementations targeting specialized markets that do not require support for floating-point or use of Advanced SIMD, ARM might produce or license an ARMv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation:

In AArch64 state

- The CPACR_EL1.FPEN field is RES0.
- The CPTR_EL2.TFP bit is RES1.
- The CPTR_EL3.TFP bit is RES1.
- Each of the ID_AA64PFR0_EL1.{AdvSIMD, FP} fields is 0b1111.
- The FPEXC32_EL2, FPCR, and FPSR registers are not implemented, and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
  - All Advanced SIMD and floating-point instructions are UNDEFINED.
  - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.
- If at least one Exception level supports execution in AArch32 state, the MVFR0_EL1, MVFR1_EL1 and MVFR2_EL1 registers are RAZ. When no Exception level supports execution in AArch32 state these registers are UNKNOWN.

In AArch32 state

See AArch32 implications of not including support for Advanced SIMD and floating-point on page G1-4696.

D1.21.4 The effects of supporting fewer than four Exception levels

The effect of implementation choices on the programmers’ model on page D1-1974 defines the permitted combinations of Exception levels in an ARMv8-A implementation.

In every implementation that supports the highest Exception level using either AArch64 state or AArch32 state, an IMPLEMENTATION DEFINED mechanism determines whether the highest implemented Exception level uses AArch64 state or AArch32 state from a Cold reset. Typically, this mechanism is a configuration input. When the highest level is configured to be AArch64 state, then after a Cold reset execution starts at the reset vector in that Exception level.

The unimplemented Exception levels have no effect on execution:

- No interrupts are routed to these Exception levels.
- No traps that target these Exception levels are active
- All systems calls to unimplemented Exception levels from lower Exception levels are treated as UNDEFINED.
- There is no support for address translation from these Exception levels.

Table D1-96 Supported combinations of Exception levels and Execution state (continued)

<tr>
<td>Two</td>
<td></td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
• Any exception return that targets an unimplemented Exception level is treated as an illegal exception return as described in *Illegal return events from AArch64 state* on page D1-1884.

• Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

___ Note ___

If, for example, EL3 is not implemented and EL2 is the highest implemented Exception level, then because none of the EL3 registers are accessible from EL2, the content of those registers is not architecturally visible.

The following subsections give more information about each of the permitted combinations of Exception levels that do not include all Exception levels.

**Behavior when EL2 is not implemented**

If EL2 is not implemented and EL3 is implemented:

• If EL1 can use AArch32 then the following registers are not RES0:
  — DACR32_EL2.
  — IFSR32_EL2.
  — FPEXC32_EL2.
  — DBGVCR32_EL2.

• The VMPIDR_EL2 and VPIDR_EL2 behave as follows:
  — Reads of VMPIDR_EL2 return the value of MPIDR_EL1, writes to VMPIDR_EL2 are ignored.
  — Reads of VPIDR_EL2 return the value of MIDR_EL1, writes to VPIDR_EL2 are ignored.

• Behavior is consistent with the HCR_EL2.RW bit taking the value of the SCR_EL3.RW bit for all purposes other than reading the HCR_EL2.

• Virtual interrupts are disabled.

• The following address translation and TLB invalidation instructions are UNDEFINED:
  — AT S1E2R and AT S1E2W.
  — TLBI VAES, TLBI VAEL, TLBI VAESIS, TLBI VAELIS, TLBI ALEL, TLBI ALELIS.

___ Note ___

No other TLB or address translation instructions become UNDEFINED with this combination of Exception levels.

• The SCR_EL3.HCE bit is RES0.

If EL2 is not implemented, regardless of whether EL3 is implemented:

• The CNTHCTL_EL2[1:0] bits are treated as if they have the value 0b11 for all purposes other than reading the CNTHCTL_EL2 register.

• The MDCR_EL2.HPMN bit taking the value of the PMCR_EL0.N bit for all purposes other than reading the value of MDCR_EL2.HPMN

**Behavior when EL3 is not implemented and EL2 is implemented**

If EL3 is not implemented and EL2 is implemented, then:

• All memory transactions can only access a single physical memory address space.

• The PE behaves as if the value of the SCR_EL3.NS bit is 1, even though the SCR_EL3 is not accessible.

This means that if the PE is part of a system that supports two Security states, it behaves as if it is in Non-secure state, and can only access Non-secure memory.
Behavior when only EL1 and EL0 are implemented

If EL3 and EL2 are not implemented, it is IMPLEMENTATION DEFINED whether the PE behaves as if the value of the SCR_EL3.NS bit is 1 or the PE behaves as if the value of the SCR_EL3.NS bit is 0.

This means that if the PE is part of a system that supports two Security states:

- If it behaves as if the value of the SCR_EL3.NS bit is 1, it can only access Non-secure memory.
- If it behaves as if the value of the SCR_EL3.NS bit is 0, it can access both Secure memory and Non-secure memory.

If the PE behaves as if the value of the SCR_EL3.NS bit is 0, then:

- The MDCR_EL3.{EPMAD, EDAD, SPME} bits behave as if they have the value 1.
- The MDCR_EL3.SPD32 field behaves as if it has the value 0b11.

Note

- The behavior described in this subsection still applies if EL1 is configured to use AArch32.
- The implementation can provide a configuration input that determines, from reset, whether the it behaves as if the value of the SCR_EL3.NS bit is 1, or as if the value of the SCR_EL3.NS bit is 0.
Chapter D2
AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates debug exceptions. This chapter describes the AArch64 self-hosted debug exception model. It is organized as follows:

Introductory information
- The debug exception enable controls on page D2-1984.

The debug Exception model
- Routing debug exceptions on page D2-1985.
- Enabling debug exceptions from the current Exception level and Security state on page D2-1987.
- The effect of powerdown on debug exceptions on page D2-1989.
- Summary of the routing and enabling of debug exceptions on page D2-1990.

The debug exceptions
- Breakpoint Instruction exceptions on page D2-1993.
- Breakpoint exceptions on page D2-1995.
- Watchpoint exceptions on page D2-2016.
- Vector Catch exceptions on page D2-2031.
- Software Step exceptions on page D2-2032.

Synchronization requirements
The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a Context synchronization event guarantees the effects of the changes:
- Synchronization and debug exceptions on page D2-2046.
D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of debug exceptions, that are taken using the exception model described in Chapter D1 The AArch64 System Level Programmers’ Model. This section introduces some terms that are used in describing self-hosted debug, and then introduces the debug exceptions. See:

- Definition of a debugger in the context of self-hosted debug.
- Context ID and Process ID.
- About debug exceptions.

D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, debugger means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

D2.1.2 Context ID and Process ID

A CONTEXTIDR_ELx identifies the current Context ID, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

In AArch64 state, the CONTEXTIDR_ELx has a single field, PROCID, that is defined as the Process Identifier (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical.

D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in stage 1 of an AArch64 translation regime are:

- Breakpoint Instruction exceptions on page D2-1981.
- Breakpoint exceptions on page D2-1981, generated by hardware breakpoints.
- Watchpoint exceptions on page D2-1981, generated by hardware watchpoints.
- Software Step exceptions on page D2-1982.

In addition, debug exceptions generated in an AArch32 translation regime might be routed to EL2 using AArch64. See Routing debug exceptions on page D2-1985. Chapter G2 describes the debug exceptions that can be generated in an AArch32 translation regime.

Vector Catch exceptions are exceptions that cannot be generated in an AArch64 translation regime but can be generated in stage 1 of an AArch32 translation regime and routed to EL2 using AArch64. Vector Catch exceptions on page D2-2031 describes the behavior for this case.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.
   See Enabling debug exceptions from the current Exception level and Security state on page D2-1987. Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.
   All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls on page D2-1984.
Note

If **halting is allowed** and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see *Halting allowed and halting prohibited* on page H2-5697.

The following list summarizes each of the debug exceptions:

### Breakpoint Instruction exceptions

*Breakpoint instructions* generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

**PE behavior**

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see *Breakpoint Instruction exceptions* on page D2-1993.

### Breakpoint exceptions

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch64 translation regime:

- **Address.** Comparisons are made with the virtual address of each instruction in the program flow.
- **Context:**
  - Context ID Match. Matches with the Context ID held in the CONTEXTIDR_EL1.
  - VMID Match. Matches with the VMID value held in the VTTBR_EL2.
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 **Debug State**.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions* on page D2-1995.

### Watchpoint exceptions

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.
For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a Linked Context type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see _Watchpoint exceptions_ on page D2-2016.

**Vector Catch exceptions**

These are not generated in an AArch64 translation regime. They can only be generated in an AArch32 translation regime. See _Vector Catch exceptions_ on page D2-2031.

**Software Step exceptions**

Software step is a resource that a debugger can use to make the PE single-step instructions. For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

**PE behavior**

Software step can only be used by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state. If debug exceptions are enabled, Software Step exceptions can be generated. If debug exceptions are disabled, software step is inactive.

For more information, see _Software Step exceptions_ on page D2-2032.

Table D2-1 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

<table>
<thead>
<tr>
<th>Debug exception</th>
<th>PE behavior if debug exceptions are:</th>
<th>Pseudocode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>Breakpoint Instruction exceptions</td>
<td>Takes the exception</td>
<td>Takes the exception</td>
</tr>
<tr>
<td>Breakpoint exceptions</td>
<td>Takes the exception^{a}</td>
<td>Ignored</td>
</tr>
<tr>
<td>Debug exception</td>
<td>PE behavior if debug exceptions are:</td>
<td>Pseudocode</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td>Watchpoint exceptions</td>
<td>Takes the exception(^a)</td>
<td>Ignored</td>
</tr>
<tr>
<td>Vector Catch exceptions</td>
<td>Takes the exception</td>
<td>Ignored</td>
</tr>
<tr>
<td>Software Step exceptions</td>
<td>Takes the exception</td>
<td>Not applicable(^b)</td>
</tr>
</tbody>
</table>

\(^a\) If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 Debug State.

\(^b\) Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.
D2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

**Breakpoint Instruction exceptions**

None. Breakpoint Instruction exceptions are always enabled.

**Breakpoint exceptions**

MDSCR_EL1.MDE, plus an enable control for each breakpoint, DBGBCR<e> EL1.E.

**Watchpoint exceptions**

MDSCR_EL1.MDE, plus an enable control for each watchpoint, DBGWCR<e> EL1.E.

**Vector Catch exceptions**

MDSCR_EL1.MDE.

**Software Step exceptions**

MDSCR_EL1.SS.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1987.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
D2.3 Routing debug exceptions

The routing of debug exceptions is as follows:

**Debug exceptions taken from Non-secure state when EL2 is implemented**

The routing of debug exceptions taken from Non-secure state depends on the values of MDCR_EL2.TDE and HCR_EL2.TGE:

If the value of \{MDCR_EL2.TDE, HCR_EL2.TGE\} is not \{0, 0\}

Debug exceptions taken from Non-secure state are routed to EL2.

Otherwise

In Non-secure state, debug exceptions behave as follows:

- Debug exceptions taken from Non-secure EL1 and Non-secure EL0 are routed to Non-secure EL1.
- Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
- All other debug exceptions are disabled from EL2 using AArch64.

--- Note ---

If EL2 is not implemented, the Effective value of HCR_EL2.TGE is 0 and the Effective value of MDCR_EL2.TDE is 0. Throughout this section, references to the values of these fields are to the Effective values of the fields.

When EL3 is implemented

Breakpoint Instruction exceptions taken from EL3 are routed to EL3.

All other debug exceptions are disabled from EL3 using AArch64.

Otherwise

Debug exceptions are routed to EL1.

This means that, for all debug exceptions, the Debug target Exception level, EL_D, is either EL1 or EL2:

- EL_D is EL2 if all of the following apply:
  - EL2 is implemented.
  - The Effective value of SCR_EL3.NS is 1.
  - The value of \{MDCR_EL2.TDE, HCR_EL2.TGE\} is not \{0, 0\}.
- Otherwise EL_D is EL1.

Table D2-2 on page D2-1986, Table D2-3 on page D2-1986, and Table D2-4 on page D2-1986 show the routing of debug exceptions. In these tables:

<table>
<thead>
<tr>
<th>TDE</th>
<th>Means the logical OR of MDCR_EL2.TDE and HCR_EL2.TGE.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NS</td>
<td>Means the Effective value of SCR_EL3.NS.</td>
</tr>
<tr>
<td>(ELx)</td>
<td>Means EL_D is ELx. However:</td>
</tr>
<tr>
<td></td>
<td>- All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Exception level.</td>
</tr>
<tr>
<td></td>
<td>- Breakpoint Instruction exceptions taken from this Exception level are routed to this Exception level.</td>
</tr>
<tr>
<td>ELx</td>
<td>Means EL_D is ELx.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

D2.3.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level.

`DebugTargetFrom()` returns the debug target Exception level for the specified Security state.

These functions are described in Chapter J1 ARMv8 Pseudocode.
D2.4 Enabling debug exceptions from the current Exception level and Security state

A debug exception can only be taken if all of the following are true:

- The OS lock is unlocked.
- `DoubleLockStatus()` == FALSE.
- The debug exception is enabled from the current Exception level.
- The debug exception is enabled from the current Security state.

Table D2-5 shows when debug exceptions are enabled from the current Exception level. In the table, EL_D is the Exception level that Table D2-2 on page D2-1986 defines.

<table>
<thead>
<tr>
<th>Current Exception level</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any Exception level that is higher than EL_D</td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
</tbody>
</table>
| EL_D                   | Enabled                  | Disabled if either of the following is true:
|                        |                        | - The Local (kernel) Debug Enable bit, MDSCR_EL1.KDE, is 0.
|                        |                        | - The Debug exception mask bit, PSTATE.D, is 1.
|                        |                        | Otherwise enabled.
|                        |                        | This means that a debugger must explicitly enable these debug exceptions from EL_D by setting MDSCR_EL1.KDE to 1 and PSTATE.D to 0. |
| Any Exception level that is lower than EL_D | Enabled | Enabled |

a. This includes EL3. EL3 is always higher than EL_D.

Note

- PSTATE.D is set to 1 at reset and on exception entry.
- ARMv8.3-NV does not introduce any changes to the debug architecture, see Nested virtualization on page D4-2188.

Table D2-6 shows when debug exceptions are enabled from the current Security state.

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

Table D2-5 Whether debug exceptions are enabled from the current Exception level

Table D2-6 Whether debug exceptions are enabled from the current Security state
D2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can set the Secure Debug Disable bit, MDCR_EL3.SDD, to 1 to disable all debug exceptions taken from AArch64 Secure state other than Breakpoint Instruction exceptions.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

--- Note ---

- If the boot software executed when reset is deasserted sets MDCR_EL3.SDD to 1, software operating at EL3 never has to switch the debug registers between Secure state and Non-secure state.

- The PE cannot take a debug exception unless it is enabled from the current Exception level. See Table D2-5 on page D2-1987.

- If either the OS lock or the OS double-lock is locked, debug exceptions other than Breakpoint Instruction exceptions are disabled.

- If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the PE behaves as if MDCR_EL3.SDD is 0.

D2.4.2 Pseudocode description of enabling debug exceptions

AArch64.GenerateDebugExceptions() determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.

AArch64.GenerateDebugExceptionsFrom() determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

These functions are described in Chapter J1 ARMv8 Pseudocode.
D2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-5805 describes the powerdown save routine and the restore routine.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and doubleLockStatus() == FALSE.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.
D2.6 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

**Breakpoint Instruction exceptions**

These are always enabled, regardless of the current Exception level and Security state. Table D2-7 shows the routing of these. In the table, n/a means not applicable.

<table>
<thead>
<tr>
<th>Current Security state</th>

<sup>a</sup> The value of `(OSLSR_EL1.OSLK == '1' || DoubleLockStatus())`.

<sup>b</sup> If EL3 is not implemented, behavior is as if this is 0.

<sup>c</sup> If `HCR_EL2.TGE` is 1, this bit is treated as being 1 other than for a direct read of `MDCR_EL2`. If EL2 is not implemented, behavior is as if TDE is 0.
D2.7 Pseudocode description of debug exceptions

\[ \text{AArch64.DebugFault}() \] returns a FaultRecord object that indicates that a memory access has generated a debug exception:

The \( \text{AArch64.Abort()} \) function processes FaultRecord objects, as described in Aborted exceptions on page D3-2079, and generates a debug exception.

\( \text{AArch64.Abort()} \) calls one of the following:

- \( \text{AArch64.BreakpointException()} \).
- \( \text{AArch64.WatchpointException()} \).
- \( \text{AArch64.VectorCatchException()} \).
- \( \text{AArch64.SoftwareStepException()} \).

These functions are defined in Chapter J1 ARMv8 Pseudocode.
D2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

For software executing in an Exception level that is using AArch64, a Breakpoint Instruction exception results from the execution of an A64 `BRK` instruction. However, within the AArch64 EL1&0 translation regime, executing a T32 or A32 `BKPT` instruction at EL0 using AArch32 generates a Breakpoint Instruction exception.

For more information about the T32 and A32 `BKPT` instructions, see:

- Breakpoint instruction in the A32 and T32 instruction sets on page G2-4751.
- BKPT instructions as the first instruction in an IT block on page G2-4752.

The following subsections describe Breakpoint Instruction exceptions in an AArch64 translation regime:

- About Breakpoint Instruction exceptions.
- Breakpoint instructions.
- Exception syndrome information and preferred return address on page D2-1994.

D2.8.1 About Breakpoint Instruction exceptions

A breakpoint is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
- The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. Breakpoint exceptions on page D2-1995 describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the debug target Exception level, EL_D, is using AArch64 or AArch32.

Note

- The debug target Exception level, EL_D, is the Exception level that debug exceptions are targeting. Routing debug exceptions on page D2-1985 describes how EL_D is derived.

- Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions on page B2-90.

D2.8.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. It is unconditional.

For details of the instruction encoding, see BRK on page C6-579.

The breakpoint instruction in the A32 and T32 instruction sets is `BKPT #<immediate>`.

For more information about the A32 and T32 breakpoint instruction, see Breakpoint instruction in the A32 and T32 instruction sets on page G2-4751.
D2.8.3 Exception syndrome information and preferred return address

See the following:
• Exception syndrome information.
• Preferred return address.

Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:
• ESR_EL1.
• ESR_EL2.
• ESR_EL3.

Note
Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

Table D2-9 shows the information that the PE records.

<table>
<thead>
<tr>
<th>ESR_ELx field</th>
<th>Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0x3C for an A64 BRK instruction.</td>
</tr>
<tr>
<td></td>
<td>• 0x38 for an A32 or T32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Length, IL</td>
<td>The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0 for a 16-bit T32 BKPT instruction.</td>
</tr>
<tr>
<td></td>
<td>• 1 for an A64 BRK instruction, or an A32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Specific Syndrome, ISS</td>
<td>The PE copies the instruction Comment field value into here, zero extended as necessary.</td>
</tr>
<tr>
<td>ISS[24:16]</td>
<td>RES0.</td>
</tr>
<tr>
<td>ISS[15:0]</td>
<td></td>
</tr>
</tbody>
</table>

Note
• If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, ESR_EL2.EC is set to the same value as if the exception was taken to EL1.
• For information about how debug exceptions can be routed to EL2, see Routing debug exceptions on page D2-1985.

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

D2.8.4 Pseudocode description of Breakpoint Instruction exceptions

AArch64.SoftwareBreakpoint() generates a Breakpoint Instruction exception that is taken to AArch64 state. This function is defined in Chapter J1 ARMv8 Pseudocode.
D2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:
• In an Exception level that is using AArch64.
• At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:
• About Breakpoint exceptions.
• Breakpoint types and linking of breakpoints on page D2-1996.
• Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2006.
• Breakpoint instruction address comparisons on page D2-2007.
• Breakpoint context comparisons on page D2-2009.
• Breakpoint usage constraints on page D2-2010.
• Exception syndrome information and preferred return address on page D2-2014.
• Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-2014.

D2.9.1 About Breakpoint exceptions

A breakpoint is an event that results from the execution of an instruction, which is based on either:
• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint exceptions are generated by Breakpoint debug events. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in Breakpoint Instruction exceptions on page D2-1993.

An implementation can include between 2-16 hardware breakpoints. ID_AA64DFR0_EL1.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:
• The Breakpoint Control Register, DBGBCR<n>_EL1. This contains controls for the breakpoint, for example an enable control.
• The Breakpoint Value Register, DBGBVR<n>_EL1. This holds the value used for breakpoint matching, that is one of:
  — An instruction virtual address.
  — A Context ID.
  — A VMID value.
  — A concatenation of both a Context ID value and a VMID value.

These registers are numbered, so that:
• DBGBCR1_EL1 and DBGBVR1_EL1 are for breakpoint number one.
• DBGBCR2_EL1 and DBGBVR2_EL1 are for breakpoint number two.
• ...
• ...
• DBGBCR<n>_EL1 and DBGBVR<n>_EL1 are for breakpoint number n.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.
For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<El1>E, is 1.
- The conditions specified in the DBGBCR<El1> are met.
- The comparison with the value held in the DBGBVR<El1> is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state. Otherwise, if debug exceptions are:

- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

**Note**

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions. However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page D2-1984 describes the enable controls for Breakpoint debug events.

### D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A context-aware breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - A Context ID match, with the value held in the CONTEXTIDR_EL1.
  - A VMID match, with the VMID value held in the VTTBR_EL2.
  - Both a Context ID match and a VMID match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

ID_AA64DFR0_EL1.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an Address breakpoint. Breakpoints that are programmed to match on anything else are categorized as Context breakpoints.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an Unlinked breakpoint.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a Linked breakpoint.
By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:

1. Program breakpoint number one to be a **Linked Address Match breakpoint**.
2. Program breakpoint number five to be a **Linked Context ID Match breakpoint**.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The **Breakpoint Type** field for a breakpoint, `DBGBCR<n>_EL1.BT`, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

*Figure D2-1* shows all of the possible breakpoint types that stage 1 of an AArch64 translation regime supports, and their associated BT field values.

![Breakpoint types and their associated BT field values](image)

*Figure D2-1* Breakpoint types and their associated BT field values

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See *Specifying the halfword-aligned address that an Address breakpoint matches on* on page D2-2008.

**Note**

Stage 1 of an AArch32 translation regimes supports two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, BT == 0b0100 and BT == 0b0101. For information about these, see Chapter G2 AArch32 *Self-hosted Debug*. These types are reserved in stage 1 of an AArch64 translation regime. See *Reserved BT values on* page D2-2011.
Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.

- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGBCR<\text{n}>_EL1.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  - DBGBCR<\text{n}>_EL1.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2006.
  - DBGBCR<\text{n}>_EL1.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.

- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.

- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.

- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints on page D2-2013.

- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.

- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

Note

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. Watchpoint exceptions on page D2-2016 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure D2-2 on page D2-1999 shows an example of permitted breakpoint and watchpoint linking.
In Figure D2-2, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

**Breakpoint types defined by DBGBCRn_EL1.BT**

The following list provides more detail about each breakpoint type:

0b0000, **Unlinked Address Match breakpoint**

Generation of a Breakpoint exception depends on both:

- **DBGBCR<n>_EL1.{SSC, HMC, PMC}**. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2006.

- A successful address match, as described in *Breakpoint instruction address comparisons* on page D2-2007.

**DBGBCR<n>_EL1.LBN** for this breakpoint is ignored.
0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>_EL1.{SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2006.
- A successful address match defined by this breakpoint, as described in Breakpoint instruction address comparisons on page D2-2007.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>_EL1.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

BT == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2006.
- A successful Context ID match, as described in Breakpoint context comparisons on page D2-2009.

The value of DBGBVR<n>_EL1.ContextID is compared with the current Context ID.

CONTEXTIDR_EL2 holds the current Context ID when all of:
- Armv8.1-VHE is implemented.
- The PE is in Non-secure state.
- EL2 using AArch64 and HCR_EL2.E2H is set to 1.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.

Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored

0b0011, Linked Context ID Match breakpoint

BT == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2007.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2009.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2021.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2009.

The value of DBGBVR<n>_EL1.ContextID is compared with the current Context ID.
CONTEXTIDR_EL2 holds the current Context ID when all of:
• The implementation includes ARMv8.1-VHE.
• The PE is in Non-secure state.
• EL2 using AArch64 and HCR_EL2.E2H is set to 1.
• The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.
Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

BT == 0b0100 is a reserved value in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-2011.

0b0100, Unlinked Address Mismatch breakpoint on page G2-4760 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0101, Linked Address Mismatch breakpoint

BT == 0b0101 is a reserved value in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-2011.

0b0101, Linked Address Mismatch breakpoint on page G2-4760 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0110, Unlinked CONTEXTIDR_EL1 Match

BT == 0b0110 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
• A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2009.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGVR<n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

— Note ——
The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b0111, Linked CONTEXTIDR_EL1 Match

BT == 0b0111 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2007.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2009.
• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2021.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2009.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGVR<n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

Note
The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2006.
• A successful VMID match, as described in Breakpoint context comparisons on page D2-2009.

DBGCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1001 is a reserved value if either:
• The breakpoint is not a context-matching breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Breakpoint instruction address comparisons on page D2-2007.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2009.
• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2021.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2009.

DBGCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.
Non-Confidential

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:
- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:
- **DBGBCR<n>._EL1.[SSC, HMC, PMC].** These define the execution conditions that the breakpoint generates a Breakpoint exception for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2006.*
- A successful Context ID match, as described in *Breakpoint context comparisons on page D2-2009.*
- A successful VMID match.

The value of **DBGBVR<n>._EL1.ContextID** is compared with the current Context ID. **CONTEXTIDR_EL2** holds the current Context ID when all of:
- The implementation includes ARMv8.1-VHE.
- The PE is in Non-secure state.
- EL2 using AArch64 and HCR_EL2.E2H is set to 1.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.

Otherwise, **CONTEXTIDR_EL1** holds the current Context ID. *Breakpoint context comparisons on page D2-2009* describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>._EL1.[LBN, BAS] for this breakpoint are ignored.

0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:
- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, one of the following applies:
- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons on page D2-2007.*
  - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons on page D2-2009.*
  - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons on page D2-2021.*
  - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons on page D2-2009.*
  - A successful VMID match defined by this breakpoint.

The value of **DBGBVR<n>._EL1.ContextID** is compared with the current Context ID. **CONTEXTIDR_EL2** holds the current Context ID when all of:
- The implementation includes ARMv8.1-VHE.
- The PE is in Non-secure state.
- EL2 using AArch64 and HCR_EL2.E2H is set to 1.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.
Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

**Breakpoint context comparisons on page D2-2009** describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

**DBGBCR<n>_EL1.\{LBN, SSC, HMC, BAS, PMC\}** for this breakpoint are ignored.

### 0b1100, Unlinked CONTEXTIDR_EL2 Match

BT == 0b1100 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>_EL1.\{SSC, HMC, PMC\}**. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful CONTEXTIDR_EL2 match, as described in **Breakpoint context comparisons on page D2-2009**.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

**Note**

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

**DBGBCR<n>_EL1.\{LBN, BAS\}** for this breakpoint are ignored.

### 0b1101, Linked CONTEXTIDR_EL2 Match

BT == 0b1101 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see **Breakpoint instruction address comparisons on page D2-2007**.
  - A successful CONTEXTIDR_EL2 match, as described in **Breakpoint context comparisons on page D2-2009**.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see **Watchpoint data address comparisons on page D2-2021**.
  - A successful CONTEXTIDR_EL2 match, as described in **Breakpoint context comparisons on page D2-2009**.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

**Note**

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

**DBGBCR<n>_EL1.\{LBN, SSC, HMC, BAS, PMC\}** for this breakpoint are ignored.
\textbf{0b1110, Unlinked Full Context ID Match}

BT == 0b1110 is a reserved value if either:
\begin{itemize}
  \item The breakpoint is not a context-aware breakpoint.
  \item The implementation does not include ARMv8.1-VHE.
\end{itemize}

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:
\begin{itemize}
  \item DBGBCR\langle n\rangle \_EL1\_\{SSC, HMC, PMC\}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
  \item A successful Context ID match, as described in \textit{Breakpoint context comparisons} on page D2-2009.
\end{itemize}

The Context ID check is made against the values in both CONTEXTIDR\_EL1 and CONTEXTIDR\_EL2. The value of DBGBVR\langle n\rangle \_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR\_EL1, and the value of DBGBVR\langle n\rangle \_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR\_EL2. Both comparisons must match for the Context ID check.

\textbf{Note}

The operation of this breakpoint does not depend on the value of HCR\_EL2.E2H.

\textbf{0b1111, Linked Full Context ID Match}

BT == 0b1111 is a reserved value if either:
\begin{itemize}
  \item The breakpoint is not a context-aware breakpoint.
  \item The implementation does not include ARMv8.1-VHE.
\end{itemize}

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, one of the following applies:
\begin{itemize}
  \item If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
  \item Generation of a Breakpoint exception depends on both:
    \begin{itemize}
      \item A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see \textit{Breakpoint instruction address comparisons} on page D2-2007.
      \item A successful Context ID match, as described in \textit{Breakpoint context comparisons} on page D2-2009.
    \end{itemize}
  \item Generation of a Watchpoint exception depends on both:
    \begin{itemize}
      \item A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see \textit{Watchpoint data address comparisons} on page D2-2021.
      \item A successful Context ID match, as described in \textit{Breakpoint context comparisons} on page D2-2009.
    \end{itemize}
\end{itemize}

The Context ID check is made against the values in both CONTEXTIDR\_EL1 and CONTEXTIDR\_EL2. The value of DBGBVR\langle n\rangle \_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR\_EL1, and the value of DBGBVR\langle n\rangle \_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR\_EL2. Both comparisons must match for the Context ID check.

\textbf{Note}

The operation of this breakpoint does not depend on the value of HCR\_EL2.E2H.

\textbf{DBGBCR\langle n\rangle \_EL1\_\{LBN, SSC, BAS, PMC\} for this breakpoint are ignored.}
D2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGBCR<n>_EL1.{SSC, HMC, PMC} defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

--- Note ---

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.

Table D2-10 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

Y Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row can generate Breakpoint exceptions in that Exception level.

- Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row cannot generate Breakpoint exceptions in that Exception level.

Res Means that the combination of HMC, SSC, and PMC is reserved. See Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-2011.

\(^a\) Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.

\(^b\) This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See **Reserved DBGBCR\(<n>\)_EL1{SSC, HMC, PMC} values** on page D2-2011.

### D2.9.4 Breakpoint instruction address comparisons

In this subsection, the term maxAddressSize represents the maximum supported virtual address size, which is 52 bits in an implementation that includes ARMv8.2-LVA and uses the 64KB translation granule, and 48 bits otherwise.

An address comparison is successful if bits [maxAddressSize:2] of the current instruction virtual address are equal to DBGBVR\(<n>_EL1[\text{maxAddressSize}:2].

---

**Note**

DBGBVR\(<n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits. DBGBVR\(<n>_EL1[1:0] are res\(_s\)0 and are ignored.

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.
Specifying the halfword-aligned address that an Address breakpoint matches on

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger must program the Byte Address Selection field, DBGBCR<n>_EL1.BAS.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0011</td>
<td>DBGBCR&lt;n&gt;_EL1</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBCR&lt;n&gt;_EL1 + 2</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBCR&lt;n&gt;_EL1</td>
<td>Use for A64 and A32 instructions.</td>
</tr>
</tbody>
</table>

If the implementation is an AArch64-only implementation, all instructions are word-aligned and DBGBCR<n>_EL1.BAS is RES1.

Figure D2-3 on page D2-2009 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with DBGBCR<n>_EL1.BAS programmed as either 0b0011 or 0b1111 generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

--- Note ---

To breakpoint on an A64 instruction, ARM recommends that the debugger programs DBGBCR<n>_EL1.BAS as 0b1111.

In the figure:

- Yes  Means that the breakpoint generates a Breakpoint exception.
- No   Means that the breakpoint does not generate a Breakpoint exception.
- UNP  Means that it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page D2-2013.
D2.9 Breakpoint exceptions

D2.9.5 Breakpoint context comparisons

The breakpoint type defined by DBGBCR<n>.BT determines what context comparison is required, if any. Table D2-12 shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table D2-12 Breakpoint Context ID and VMID comparison tests

<table>
<thead>
<tr>
<th>DBGBCR&lt;n&gt;.BT</th>
<th>Test required for successful context comparison</th>
</tr>
</thead>
</table>
| 0b001x      | • When ARMv8.1-VHE is implemented, EL2 is using AArch64, the Effective value of HCR_EL2.E2H is 1, and either the PE is executing at EL0 with HCR_EL2.TGE set to 1, or the PE is executing at EL2, CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID value.  
  • Otherwise, CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value. |
| 0b011x      | CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value. |
| 0b100x      | VTTBR_EL2.VMID must match the DBGBVR<n>_EL1.VMID value. |
| 0b101x      | CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value and VTTBR_EL2.VMID must match the DBGBVR<n>_EL1.VMID value. |
| 0b110x      | CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID2 value, DBGBVR<n>_EL1[63:32]. |
| 0b111x      | Both:  
  • CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value, DBGBVR<n>_EL1[31:0].  
  • CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID2 value, DBGBVR<n>_EL1[63:32]. |

No Context ID or VMID comparison is required for other valid DBGBCR<n>.BT values.

In ARMv8.0, context breakpoints do not generate Breakpoint exceptions when execution is in EL2 using either Execution state, or when execution is in EL3 using AArch64.
Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR_EL1 and any of:
  - The PE is executing at EL3 using AArch64.
  - The PE is executing at EL2.
  - ARMv8.1-VHE is implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and
    HCR_EL2.{E2H, TGE} == {1, 1}.

- The comparison uses the value of CONTEXTIDR_EL2 and any of:
  - ARMv8.1-VHE is not implemented.
  - The PE is in Secure state.
  - EL2 is using AArch32.

- The comparison uses the current VMID value and any of:
  - EL2 is not implemented.
  - The PE is in Secure state.
  - The PE is executing at EL2.
  - ARMv8.1-VHE is implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and
    HCR_EL2.{E2H, TGE} == {1, 1}.

The following Context breakpoint types do not generate Breakpoint exceptions in Secure state:

- VMID Match breakpoints.
- VMID and Context ID Match breakpoints.

__________ Note __________

- For all Context breakpoints, DBGBCR<n>_EL1.BAS is RES1 and is ignored.
- For Linked Context breakpoints, DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

D2.9.6 Breakpoint usage constraints

See the following sections:

- Reserved DBGBCR<n>_EL1.BT values on page D2-2011.
- Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-2011.
- Reserved DBGBCR<n>_EL1.BAS values on page D2-2012.
- Reserved DBGBCR<n>_EL1.LBN values on page D2-2012.
- Other usage constraints for Address breakpoints on page D2-2013.
- Other usage constraints for Context breakpoints on page D2-2013.
Reserved DBGBCR<n>_EL1.BT values

Table D2-13 shows when particular DBGBCR<n>_EL1.BT values are reserved.

<table>
<thead>
<tr>
<th>BT value</th>
<th>Breakpoint type</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>

<td>If ARMv8.1-VHE is not implemented, or the breakpoint is not context-aware</td>
</tr>
</tbody>
</table>

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>_EL1.

- For a direct or external read of DBGBCR<n>_EL1, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values

Table D2-14 shows when particular combinations of DBGBCR<n>_EL1.{SSC, HMC, PMC} are reserved in stage 1 of an AArch64 translation regime.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10</td>
<td>When EL3 is not implemented and EL2 is implemented</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b0</td>
<td>When both of EL2 and EL3 are not implemented</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b0</td>
<td>When EL2 is not implemented</td>
</tr>
<tr>
<td>Combinations not included in Table D2-10 on page D2-2006</td>
<td>Always</td>
</tr>
</tbody>
</table>
For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
  - A direct or external read of DBGBCR<\text{n}> EL1.{SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.

- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of DBGBCR<\text{n}> EL1.{SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.

- A direct or external read of DBGBCR<\text{n}> EL1.{SSC, HMC, PMC} returns UNKNOWN values.

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR<\text{n}> EL1.BAS values**

In an AArch64-only implementation, DBGBCR<\text{n}> EL1.BAS for all breakpoints is RES1.

Otherwise:

**For all Context breakpoints**

- DBGBCR<\text{n}> EL1.BAS is RES1 and is ignored.

**For all Address breakpoints**

- Table D2-11 on page D2-2008 gives the valid values of the DBGBCR<\text{n}> EL1.BAS field.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BAS value that is not reserved, other than for a direct or external read of DBGBCR<\text{n}> EL1.

- A direct or external read of DBGBCR<\text{n}> EL1.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

**Reserved DBGBCR<\text{n}> EL1.LBN values**

**For all Context breakpoints**

- DBGBCR<\text{n}> EL1.LBN reads UNKNOWN and its value is ignored.
For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<\text{n}>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGBCR<\text{n}>_EL1.LBN return an UNKNOWN value and behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

* Disabled.
* Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Address breakpoints

DBGBCR<\text{n}>_EL1.LBN reads UNKNOWN and its value is ignored.

Other usage constraints for Address breakpoints

For all Address breakpoints

* DBGBVR<\text{n}>_EL1[1:0] are RES0 and are ignored.
* If the implementation supports AArch32 state:
  * For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
  * If DBGBCR<\text{n}>,BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<\text{n}>[48:2]:00) + 2). For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<\text{n}>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.

For Linked Context breakpoints

If no Linked Address breakpoints or Linked watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.
D2.9.7 Exception syndrome information and preferred return address

See the following:
• Exception syndrome information.
• Preferred return address.

Exception syndrome information

On taking a Breakpoint exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:
• ESR_EL1.
• ESR_EL2.

Note
Breakpoint exceptions cannot be taken to EL3 using AArch64.

Table D2-15 shows the information that the PE records.

Table D2-15 Information recorded in the ESR_ELx

<table>
<thead>
<tr>
<th>ESR_ELx field</th>
<th>Information recorded in ESR_EL1 or ESR_EL2.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0x30, if the exception was taken from a lower Exception level.</td>
</tr>
<tr>
<td></td>
<td>• 0x31, if the exception was taken without a change of Exception level.</td>
</tr>
<tr>
<td>Instruction Length, IL</td>
<td>The PE sets this to 1.</td>
</tr>
<tr>
<td>Instruction Specific Syndrome, ISS</td>
<td>ISS[24:6] RES0.</td>
</tr>
<tr>
<td></td>
<td>ISS[5:0] Instruction Fault Status Code (IFSC). The PE sets this to the code for a debug exception, 0b100010.</td>
</tr>
</tbody>
</table>

Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch64 state

AArch64.BreakpointValueMatch() tests the value in DBGVR<n>_EL1.

AArch64.StateMatch() tests the values in DBGBCR<n>_EL1.{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, AArch64.StateMatch() tests the values in DBGWCR<n>_EL1.{SSC, HMC, PAC} and, if the watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

AArch64.BreakpointMatch() tests a committed instruction against all breakpoints.

AArch64.CheckBreakpoint() generates a Breakpoint exception if all of the following are true:
• MDSCR_EL1.MDE is 1.
• Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state on page D2-1987.
• All of the conditions required for Breakpoint exception generation are met. See About Breakpoint exceptions on page D2-1995.
Note

`AArch64.CheckBreakpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

`AArch64.BreakpointException()` is called to generate a Breakpoint exception.

These functions are defined in Chapter J1 ARMv8 Pseudocode.
D2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:
• In an Exception level that is using AArch64.
• At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:
• About Watchpoint exceptions.
• Watchpoint types and linking of watchpoints on page D2-2018.
• Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2019.
• Watchpoint data address comparisons on page D2-2021.

D2.10.1 About Watchpoint exceptions

A watchpoint is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as data breakpoints.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a Watchpoint debug event on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, ID_AA64DFR0_EL1.WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

• The Watchpoint Control Register, DBGWCR<n>_EL1. This contains controls for the watchpoint, for example an enable control.
• The Watchpoint Value Register, DBGWVR<n>_EL1. This holds the data virtual address used for watchpoint matching.

These registers are numbered, so that:
• DBGWCR1_EL1 and DBGWVR1_EL1 are for watchpoint number one.
• DBGWCR2_EL2 and DBGWVR2_EL1 are for watchpoint number two.
• …
• …
• DBGWCR<n>_EL1 and DBGWVR<n>_EL1 are for watchpoint number n.

A watchpoint can:
• Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
• Link to a Linked Context breakpoint, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.
A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the Byte Address Select field, DBGWCR<\texttt{n}>_EL1.BAS, to select the bytes. See Programming a watchpoint with eight bytes or fewer on page D2-2022.

- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

  A debugger uses the MASK field, DBGWCR<\texttt{n}>_EL1.MASK, to program a watchpoint with eight bytes to 2GB. See Programming a watchpoint with eight or more bytes on page D2-2023.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint debug events is CONSTRAINED UNPREDICTABLE. See Programming dependencies of the BAS and MASK fields on page D2-2027.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, DBGWCR<\texttt{n}>_EL1.E, is 1.
- The conditions specified in the DBGWCR<\texttt{n}>_EL1 are met.
- The comparison with the address held in the DBGWVR<\texttt{n}>_EL1 is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint also are successful. See Figure D2-2 on page D2-1999. See also Breakpoint context comparisons on page D2-2009.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

--- Note ---

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

---

*The debug exception enable controls on page D2-1984 describes the enable controls for Watchpoint debug events.*
D2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

• Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
• Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The *Watchpoint Type* field for a watchpoint, DBGWCR<el1>_WT, controls whether the watchpoint is enabled for linking. If DBGWCR<el1>_WT is 1, the watchpoint is enabled for linking.

### Rules for linking watchpoints

The rules for watchpoint linking are as follows:

• Only Linked watchpoints can be linked.
• A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, DBGWCR<el1>_LBN, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  — DBGWCR<el1>_WT.{SSC, HMC, PAC} for the Linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page D2-2019.
  — DBGBCR<el1>._SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
• A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
• If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINTED UNPREDICTABLE. See *Watchpoint usage constraints* on page D2-2026.
• If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
• Multiple Linked watchpoints can link to a single Linked Context breakpoint.

**Note**

Multiple Address breakpoints can also link to a single Linked Context breakpoint. *Breakpoint exceptions on page D2-1995* describes breakpoints.

Figure D2-2 on page D2-1999 shows an example of permitted watchpoint linking.
D2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2 in Non-secure state.

`DBGWCR<n>_EL1.{SSC, HMC, PAC}` define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

Note

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Exception levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level at which the access was made.

Note

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at EL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on EL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A64 Load unprivileged and Store unprivileged instructions are `LDTR` and `STTR`.

Table D2-16 on page D2-2020 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

<table>
<thead>
<tr>
<th>Y or -</th>
<th>Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y</td>
<td>Can generate Watchpoint exceptions in that Exception level.</td>
</tr>
<tr>
<td>-</td>
<td>Cannot generate Watchpoint exceptions in that Exception level.</td>
</tr>
</tbody>
</table>

Res

Means that the combination of HMC, SSC, and PAC is reserved. See Reserved `DBGWCR<n>_EL1.{SSC, HMC, PAC}` values on page D2-2026.

<sup>a</sup> Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PAC that generate Watchpoint exceptions at EL3 using AArch64.

<sup>b</sup> This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See Reserved `DBGWCR<n>_EL1/EL2/SSC, HMC, PAC` values on page D2-2026.
D2.10.4 Watchpoint data address comparisons

In this subsection, the term `maxAddressSize` represents the maximum supported virtual address size, which is:

- 52 bits in an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule.
- 48 bits otherwise.

An address comparison is successful if bits `[maxAddressSize:2]` of the current data virtual address are equal to `DBGWVR<ν>_EL1[maxAddressSize:2]`, taking into account all of the following:

- The size of the access. See "Size of the data access." If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, data addresses are zero-extended before comparison with the watchpoint.

- The bytes selected by `DBGWVR<ν>_EL1.BAS`. See "Programming a watchpoint with eight bytes or fewer on page D2-2022.

- Any address ranges indicated by `DBGWVR<ν>_EL1.MASK`. See "Programming a watchpoint with eight or more bytes on page D2-2023.

--- Note ---
- `DBGWVR<ν>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits.
- `DBGWVR<ν>_EL1[1:0]` are `RES0` and are ignored

---

Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. See Example D2-1.

**Example D2-1**

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address 0x1009 is accessed.

2. The PE accesses the unaligned doubleword starting at address 0x1003.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by `DC ZVA` instructions is the DC ZVA block size that `DCZID_EL0.BS` defines.

The size of data accesses initiated by `DC IVAC` instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that `CTR_EL0.DminLine` defines.
  - 2KB.
- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is `(size - 1)` bytes above the lowest address accessed.

See also, "Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction on page D2-2026."
Programm a watchpoint with eight bytes or fewer

The Byte Address Select field, DBGWCR<n>_EL1.BAS, selects which bytes in the doubleword starting at the address contained in the DBGWVR<n>_EL1 the watchpoint generates Watchpoint exceptions for.

If the address programmed into the DBGWVR<n>_EL1 is:

- Doubleword-aligned:
  - All eight bits of DBGWCR<n>_EL1.BAS are used, and the descriptions given in Table D2-17 apply.
- Word-aligned but not doubleword-aligned:
  - Only DBGWCR<n>_EL1.BAS[3:0] are used, and the descriptions given in Table D2-18 apply. In this case, DBGWCR<n>_EL1.BAS[7:4] are RES0.

| Table D2-17 Supported BAS values when the DBGWVRn_EL1 address alignment is doubleword |
|---------------------------------|---------------------------------|
| BAS value | Description |
| 0b00000000 | Watchpoint never generates a Watchpoint exception. |
| BAS[0] == 1 | Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[maxAddressSizea:3]:00 is accessed. |
| BAS[1] == 1 | Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[maxAddressSizea:3]:01 is accessed. |
| BAS[2] == 1 | Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[maxAddressSizea:3]:10 is accessed. |
| BAS[3] == 1 | Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[maxAddressSizea:3]:11 is accessed. |
| BAS[4] == 1 | Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[maxAddressSizea:3]:10 is accessed. |
| BAS[5] == 1 | Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[maxAddressSizea:3]:11 is accessed. |
| BAS[6] == 1 | Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[maxAddressSizea:3]:10 is accessed. |
| BAS[7] == 1 | Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[maxAddressSizea:3]:11 is accessed. |

a. maxAddressSize is 52 bits in an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, and 48 bits otherwise.

| Table D2-18 Supported BAS values when the DBGWVRn_EL1 address alignment is word |
|---------------------------------|---------------------------------|
| BAS valuea | Description |
| 0b00000000 | Watchpoint never generates a Watchpoint exception |
| BAS[0] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>_EL1[maxAddressSizeb:2]:00 is accessed. |
| BAS[1] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>_EL1[maxAddressSizeb:2]:01 is accessed. |
| BAS[2] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>_EL1[maxAddressSizeb:2]:10 is accessed. |
| BAS[3] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>_EL1[maxAddressSizeb:2]:11 is accessed. |

a. DBGWCR<n>_EL1.BAS[7:4] are RES0.
b. maxAddressSize is 52 bits in an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, and 48 bits otherwise.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see Other usage constraints on page D2-2028.
When programming the BAS field with anything other than \(0b11111111\), a debugger must program \(\text{DBGWCR}_n._\text{EL1}.\text{MASK}\) to be \(0b00000\). See Programming dependencies of the BAS and MASK fields on page D2-2027.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the \(\text{DBGWVR}_n._\text{EL1}[\text{maxAddressSize}:3]\). See Example D2-1 on page D2-2021.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address \(0x1003\), program:
  - \(\text{DBGWVR}_n._\text{EL1}\) with \(0x1000\).
  - \(\text{DBGWCR}_n._\text{EL1}.\text{BAS}\) to be \(0b00001000\).

- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses \(0x2003\), \(0x2004\) and \(0x2005\), program:
  - \(\text{DBGWVR}_n._\text{EL1}\) with \(0x2000\).
  - \(\text{DBGWCR}_n._\text{EL1}.\text{BAS}\) to be \(0b00111000\).

- If the address programmed into the \(\text{DBGWVR}_n._\text{EL1}\) is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program \(\text{DBGWCR}_n._\text{EL1}.\text{BAS}\) to be \(0b00001111\).
  - To generate a Watchpoint exception when any byte in the word starting at address \(\text{DBGWVR}_n._\text{EL1}[31:3]:100\) is accessed, program \(\text{DBGWCR}_n._\text{EL1}.\text{BAS}\) to be \(0b11110000\).

---

**Note**

ARM deprecates programming a \(\text{DBGWVR}_n._\text{EL1}\) with an address that is not doubleword-aligned.

---

**Programming a watchpoint with eight or more bytes**

A debugger can use the MASK field, \(\text{DBGWCR}_n._\text{EL1}.\text{MASK}\), to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.

- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<table>
<thead>
<tr>
<th>MASK</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(0b00000)</td>
<td>No bits are masked.</td>
</tr>
<tr>
<td>(0b00001)</td>
<td>Reserved.</td>
</tr>
<tr>
<td>(0b00010)</td>
<td>Reserved.</td>
</tr>
<tr>
<td>(0b00011)</td>
<td>Three least significant bits are masked.</td>
</tr>
<tr>
<td>(0b00100)</td>
<td>Four least significant bits are masked.</td>
</tr>
<tr>
<td>(0b00101)</td>
<td>Five least significant bits are masked.</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>(0b11111)</td>
<td>31 least significant bits are masked.</td>
</tr>
</tbody>
</table>
If \( n \) least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address \( \text{DBGWVR}<n>\text{EL1}[\text{maxAddressSize}:n]:000… \)
- Address \( \text{DBGWVR}<n>\text{EL1}[\text{maxAddressSize}:n]:111… \)
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between \( \text{DBGWVR}<n>\text{EL1}[\text{maxAddressSize}:4]:0000 \) and \( \text{DBGWVR}<n>\text{EL1}[\text{maxAddressSize}:4]:1111 \), including these addresses.

---

**Note**

- The 17 most significant bits cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see *Reserved DBGWCR<n>_EL1.MASK values* on page D2-2028.

---

When masking address bits, a debugger must both:

- Program \( \text{DBGWCR}<n>_\text{EL1}.\text{BAS} \) to be \( \text{0b11111111} \). See *Programming dependencies of the BAS and MASK fields* on page D2-2027.
- In the \( \text{DBGWVR}<n>_\text{EL1} \), set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see *Other usage constraints* on page D2-2028.

---

**D2.10.5 Determining the memory location that caused a Watchpoint exception**

On taking a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- \( \text{FAR}_\text{EL1} \), if the exception is taken to EL1.
- \( \text{FAR}_\text{EL2} \), if the exception is taken to EL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the *EDWAR*.

For more information, see the subsections that follow. These are:

- *Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions*
- *Address recorded for Watchpoint exceptions generated by data cache maintenance instructions* on page D2-2025

---

**Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions**

---

Despite its mnemonic, \text{DC ZVA} is not a data cache maintenance instruction.

---

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access that triggered the watchpoint.
  - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.
Within a naturally-aligned block of memory that is all of the following:
- A power-of-two size.
- No larger than the DC ZVA block size.
- Contains a watchpointed address accessed by the memory access.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

**Example D2-2 Address recorded for a watchpoint programmed on 0x8019**

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:
- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
- 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.

**Address recorded for Watchpoint exceptions generated by data cache maintenance instructions**

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

**D2.10.6 Watchpoint behavior on other instructions**

Under normal operating conditions, the following do not generate Watchpoint exceptions:
- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch memory instructions.
- All data cache maintenance instructions except DC IVAC.
- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a DC IVAC instruction can generate a Watchpoint.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

--- **Note** ---

The DC ZVA, Data Cache Zero by VA instruction is not a data cache maintenance instruction.

See also the following subsections:
- Watchpoint behavior on accesses by Store-Exclusive instructions on page D2-2026.
- Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction on page D2-2026.
Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction

DC IVAC and DC ZVA operations are treated as data stores. This means that for a watchpoint to match on an access caused by one of these instructions, the debugger must program DBGWCR<\n>_EL1.LSC to be one of the following:

- 10 Match on data stores.
- 11 Match on data stores and data loads.

--- Note ---

For the size of data accesses performed by the DC IVAC instruction and the DC ZVA instruction, see Watchpoint data address comparisons on page D2-2021. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

D2.10.7 Watchpoint usage constraints

See the following:

- Reserved DBGWCR<\n>_EL1.{SSC, HMC, PAC} values.
- Reserved DBGWCR<\n>_EL1.LBN values on page D2-2027.
- Programming dependencies of the BAS and MASK fields on page D2-2027.
- Reserved DBGWCR<\n>_EL1.BAS values on page D2-2027.
- Reserved DBGWCR<\n>_EL1.MASK values on page D2-2028.
- Other usage constraints on page D2-2028.

Reserved DBGWCR<\n>_EL1.{SSC, HMC, PAC} values

Table D2-19 shows when particular combinations of DBGWCR<\n>_EL1.{SSC, HMC, PAC} are reserved.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>

<td>Always</td>
</tr>
</tbody>
</table>

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<\n>_EL1.
• For a direct or external read of DBGWCR<n>_EL1, if the reserved combination:
  — Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
  — Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGWCR<n>_EL1.LBN values

For Linked Watchpoints

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGWCR<n>_EL1.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

• Disabled
• Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Watchpoints

For Unlinked watchpoints, DBGWCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

• The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
• The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n>_EL1 the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

• MASK field, it must program BAS to be 0b11111111, so that all bytes in the doubleword or word are selected.
• BAS field, it must program MASK to be 0b00000, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to 0b11111111, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

Reserved DBGWCR<n>_EL1.BAS values

The BAS field must be programmed with a value Zeros(8-n-m):Ones(n):Zeros(m), where:

• n is a non-zero positive integer less-than-or-equal-to 8.
• m is a positive integer less-than 8.
• n+m is less-than-or-equal-to 8.

All other values are reserved.

Note

If x is zero, then Zeros(x) is an empty bitstring.
If DBGWVR<n>_EL1[2] is 1, DBGWCR<n>_EL1.BAS[7:4] are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

• It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWVR<n>_EL1.

• A direct or external read of DBGWCR<n>_EL1.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved DBGWCR<n>_EL1.MASK values

If a watchpoint is programmed with a reserved MASK value:

• The watchpoint must behave as if it is either:
  — Disabled.
  — Programmed with an UNKNOWN value that is not reserved, that might be 0b00000, other than for a direct or external read of DBGWCR<n>_EL1.

• A direct or external read of DBGWCR<n>_EL1.MASK returns an UNKNOWN value.

Other usage constraints

For all watchpoints:

• DBGWVR<n>_EL1[1:0] are RES0 and are ignored.

• If DBGWCR<n>_EL1.MASK is nonzero, and any masked bits of DBGWVR<n>_EL1 are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.

• A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>_EL1.LSC is 0b00.

D2.10.8 Exception syndrome information and preferred return address

See the following:

• Exception syndrome information.
• Preferred return address on page D2-2029.

Exception syndrome information

On taking a Watchpoint exception, the PE records all of the following:

• Information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to.

• An address that the debugger can use to determine the memory location that caused the exception. The PE records this in a Fault Address Register (FAR).

The ESR and FAR used is either:

• ESR_EL1 and FAR_EL1, if the exception is taken to EL1.
• ESR_EL2 and FAR_EL2, if the exception is taken to EL2.

——— Note ————
Watchpoint exceptions cannot be taken to EL3 using AArch64.
Table D2-20 shows the recorded information.

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>ISS[5:0] Data Fault Status Code (DFSC). The PE sets this to the code for a debug exception, 0b100010.</td>
</tr>
</tbody>
</table>

Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

**D2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch64 state**

_AArch64.WatchpointByteMatch()_ tests an individual byte accessed by an operation.

_AArch64.StateMatch()_ tests the values in DBGWCR<n>_EL1.\{HMC, SSC, PAC\}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

_AArch64.WatchpointMatch()_ tests the value in DBGWVR<n>_EL1.

_AArch64.CheckWatchpoint()_ generates a FaultRecord that _AArch64.Abort()_ raises a Watchpoint exception for if all of the following are true:

- MDSCR_EL1.MDE is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state on page D2-1987*.
- All of the conditions required for Watchpoint exception generation are met. See *About Watchpoint exceptions on page D2-2016*.

---

**Note**

_AArch64.CheckWatchpoint()_ might halt the PE and cause it to enter Debug state. External debug uses Debug state.
AArch64.WatchpointException() is called to generate a Watchpoint exception.

These functions are defined in Chapter J1 *ARMv8 Pseudocode*. 
D2.11 Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 translation regimes.

Note
This means that they are never taken to EL1 using AArch64 and are only supported if at least EL1 using AArch32 is supported.

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64. See Routing debug exceptions on page D2-1985.

AArch64.VectorCatchException() is called to generate a Vector Catch exception.

Vector Catch exceptions on page G2-4795 describes Vector Catch exceptions.
D2.12 Software Step exceptions

The following subsections describe Software Step exceptions:

- About Software Step exceptions.
- Rules for setting MDSCR_EL1.SS to 1.
- The software step state machine on page D2-2033.
- Entering the active-not-pending state on page D2-2034.
- Behavior in the active-not-pending state on page D2-2038.
- Entering the active-pending state on page D2-2040.
- Behavior in the active-pending state on page D2-2040.
- Stepping T32 IT instructions on page D2-2041.
- Exception syndrome information and preferred return address on page D2-2041.
- Additional considerations on page D2-2043.
- Pseudocode description of Software Step exceptions on page D2-2045.

D2.12.1 About Software Step exceptions

Software step is an ARMv8-A resource that a debugger can use to make the PE single-step instructions. For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
   b. Executes an exception return instruction, ERET, to branch to the instruction to be single-stepped in the software being debugged.

2. The PE then:
   a. Executes the instruction to be single-stepped.
   b. Takes a Software Step exception on the next instruction, returning control to the debugger.

However, another exception might be generated while the instruction is being stepped. This exception is either:

- A synchronous exception that is generated by the instruction being stepped.
- An asynchronous exception that is taken before or after the instruction being stepped.

The PE can only take a Software Step exception if debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state on page D2-1987.

A state machine describes the behavior of software step, shown in The software step state machine on page D2-2033.

Throughout this Software Step exceptions section, including in all subsections, EL₁₀ means the Exception level that Software Step exceptions are targeting. Routing debug exceptions on page D2-1985 defines EL₁₀ as the debug target Exception level.

D2.12.2 Rules for setting MDSCR_EL1.SS to 1

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR_EL1.SS to 1.

The Exception level that hosts the debugger software must be using AArch64.
D2.12.3 The software step state machine

In Figure D2-4:
- The OS Lock is unlocked and `DoubleLockStatus() == FALSE`.
- The PE is not in Secure state with `MDCR_EL3.SDD` set to 1. That is, the PE is in Non-secure state, or is in Secure state with `MDCR_EL3.SDD` set to 0, or the implementation does not include EL3.

Figure D2-4 Software step state machine

For a description of when debug exceptions are enabled or disabled from an Exception level, see `Enabling debug exceptions from the current Exception level and Security state` on page D2-1987.

For more information about how a step is completed, see `Behavior in the active-not-pending state` on page D2-2038.
The software step states are:

**Inactive**  
Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:

- MDSCR_EL1.SS is 0.
- EL_D is using AArch32.
- Debug exceptions are disabled from the current Exception level or Security state.

**Active-not-pending**  
None of the conditions mentioned in *Inactive* are true, therefore software step is active. The current instruction is the instruction to be stepped.

**Active-pending**  
None of the conditions mentioned in *Inactive* are true, therefore software step is active. A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not-pending state or the active-pending state depends on PSTATE.SS. Table D2-21 shows this.

<table>
<thead>
<tr>
<th>EL_D using:</th>

<td>1</td>
<td>0</td>
<td>Active-pending</td>
</tr>
</tbody>
</table>

**D2.12.4 Entering the active-not-pending state**

Software step can only enter the active-not-pending state from the inactive state.

Software step:

- Enters the active-not-pending state when an *ERET* instruction writes 1 to PSTATE.SS, by copying from SPSR_ELx.SS when it restores PSTATE.
- Might enter the active-not-pending state on exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 1. See *Exiting Debug state* on page H2-5733.

An *ERET* instruction only copies 1 from SPSR_ELx.SS to PSTATE.SS if all of the following are true:

- MDSCR_EL1.SS is 1.
- EL_D is using AArch64.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the *ERET* instruction targets.

Otherwise, *ERET* instructions set PSTATE.SS to 0, regardless of the value of SPSR_ELx.SS.

Table D2-22 on page D2-2035 shows this. In the table:

- **Lock**  
  Means the value of (OSLSR_EL1.OSLK == ’1’ || DoubleLockStatus()).

- **NS**  
  Is SCR_EL3.NS.

- **SDD**  
TDE

Is MDCR_EL2.TDE. See Routing debug exceptions on page D2-1985.

For:

- **SCR_EL3.NS == 0 or MDCR_EL2.TDE == 0, and EL1 using AArch64, so that EL_D is EL1 using AArch64**, Table D2-23 on page D2-2036 shows the value an ERET writes to PSTATE.SS.

- **SCR_EL3.NS == 1 and MDCR_EL2.TDE == 1 and EL2 using AArch64, so that EL_D is EL2 using AArch64**, Table D2-24 on page D2-2037 shows the value an ERET writes to PSTATE.SS.

In both tables:

**From EL**

Means the Exception level at which the PE executes the ERET instruction.

**Target EL**

Is the target Exception level of the ERET.

**Note**

If the ERET is an illegal exception return, the target Exception level of the ERET is the current Exception level. See Illegal return events from AArch64 state on page D1-1884.

**KDE**

Is MDSCR_EL1.KDE. See Enabling debug exceptions from the current Exception level and Security state on page D2-1987.

ᵃ. Because MDSCR_EL1.SS == 1, it means that the ERET is itself being stepped.
ᵇ. Depends on SPSR_EL2.D.

---

**Note**

No AArch32 instruction can set PSTATE.SS to 1.
D2.12.5   Behavior in the active-not-pending state

In this state, the PE does one of the following:

• Executes the instruction to be stepped and either:
  — Completes it without taking a synchronous exception.
  — Takes a synchronous exception if the instruction generates one.

• Takes an asynchronous exception without executing any instructions.

• Enters Debug state because of a *Halting debug event*.

If the PE executes the instruction without taking any exceptions, then the PE sets PSTATE.SS to 0, meaning that after the instruction has been executed:

• If the instruction has disabled debug by setting PSTATE.D to 1 then software step advances to the inactive state.

• If the instruction disables software step by a direct write to a System register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS, then software step might advance to the inactive state. These writes require explicit synchronization to guarantee their effect. See *Synchronization and the software step state machine* on page D2-2044.

• Otherwise, software step advances to the active-pending state. See *Behavior in the active-pending state* on page D2-2040.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

• If the PE takes an exception to an Exception level that is using AArch64.

• If the PE takes an exception to an Exception level that is using AArch32 on page D2-2039.

If the PE enters Debug state because of a Halting debug event, behavior is as described in *Entering Debug state and Software Step* on page H2-5706.

If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

• Sets SPSR_ELx.SS to 0 or 1, depending on the exception. See Table D2-25.

• Sets PSTATE.SS to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:
  - **Enabled**  Software step enters the active-pending state.
  - **Disabled**  Software step enters the inactive state.

In either case, on taking the exception, a step is complete.

• Sets PSTATE.D to 1.

<table>
<thead>
<tr>
<th>Exception description</th>
<th>Exceptions</th>
<th>SPSR_ELx.SS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.</td>
<td>Supervisor Call (SVC) exceptions. Hypervisor Call (HVC) exceptions. Secure Monitor Call (SMC) exceptions.</td>
<td>0</td>
</tr>
<tr>
<td>Exceptions whose preferred return address is the address of the instruction to be stepped.</td>
<td>All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.</td>
<td>1</td>
</tr>
</tbody>
</table>
Note

If an SMC instruction executed at Non-secure EL1 is trapped to EL2 because HCR_EL2.TSC is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so SPSR_ELx.SS is set to 1, not 0.

If the PE takes an exception to an Exception level that is using AArch32

This can only happen when all of the following is true:

- EL2 is implemented and is using AArch64, the PE is executing in Non-secure state, and MDCR_EL2.TDE is 1. Because MDCR_EL2.TDE is 1, EL_D is EL2.
- The exception is taken to Non-secure EL1 using AArch32.

As part of exception entry, the PE sets PSTATE.SS to 0. This causes software step to enter the active-pending state.

Note

- Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because EL_D is EL2, and debug exceptions are always enabled from Exception levels that are lower than EL_D.
- AArch32 SPSRs have no SS bit. Where an SPSR_ELx register architecturally maps to an AArch32 SPSR_<mode> register, SPSR_ELx.SS maps to SPSR_<mode>[21]. SPSR_<mode>[21] is always RES0. The PE always sets SPSR_<mode>[21] to 0 on taking an exception to an Exception level that is using AArch32.

Summary of behavior in the active-not-pending state

Table D2-26 summarizes behavior in the active-not-pending state.

<sup>a</sup> For the No exception rows, this column shows the effect of the event.
For the Exception rows, this column shows the exception taken.

<sup>b</sup> Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See Figure D2-4 on page D2-2033.

<sup>c</sup> SPSR_<mode>[21] is RES0.
D2.12.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- MDSCR_EL1.SS is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

While software step is in the active-not-pending state

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.

While software step is in the active-pending state

The PE takes an asynchronous exception.

While software step is in the inactive state

The PE executes either:

- An ERET instruction when SPSR_ELx.SS is 0.
- An instruction that enables debug by setting PSTATE.D to 0.

Note

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to Non-secure EL1 when MDCR_EL2.TDE is 1. Otherwise, debug exceptions are masked by PSTATE.D, therefore they would be disabled from the target Exception level of the exception.

In addition, software step might enter the active-pending state either:

- After a direct write to a System register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine on page D2-2044.
- On exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 0. See Exiting Debug state on page H2-5733.

D2.12.7 Behavior in the active-pending state

When the PE is in the active-pending state, a Software Step exception is taken before the PE executes an instruction. The Software Step exception has higher priority than all other types of synchronous exception. However, the prioritization of this exception with respect to any unmasked pending asynchronous exception is not defined by the architecture.

For more information, see the following:

- Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895.
- Prioritization and recognition of interrupts on page D1-1908.
- Architectural requirements for taking asynchronous exceptions on page G1-4629.
### D2.12.8 Stepping T32 IT instructions

The ARMv8-A architecture permits a combination of an IT instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is **IMPLEMENTATION DEFINED** whether:

- The PE considers this combination to be one instruction.
- The PE considers this combination to be two instructions.

In an implementation that supports the ITD control, that can disable some uses of the IT instruction, it is then **IMPLEMENTATION DEFINED** whether this behavior depends on the value of the applicable ITD field. For example:

- The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be one instruction when the applicable ITD field is 1, and two instructions when it is 0.

The applicable ITD field is one of:

- `SCTLR_EL1.ITD` if execution is at EL0 using AArch32 when EL1 is using AArch64.
- `SCTLR.ITD` if execution is at Non-secure EL0 or EL1 using AArch32.
- `HSCTLR.ITD` if execution is at Non-secure EL2 using AArch32.

### D2.12.9 Exception syndrome information and preferred return address

See the following:

- *Exception syndrome information*.
- *Preferred return address* on page D2-2043.

#### Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- `ESR_EL1`
- `ESR_EL2`

**Note**

Software Step exceptions cannot be taken to EL3.

Table D2-27 on page D2-2042 shows the information that the PE records.
When an instruction has been stepped, the PE sets:

- The value of ISS.ISV to 1, to indicate that the EX bit is valid.
- The value of EX to indicate whether the instruction stepped was a Load-Exclusive instruction, using the ISS.EX values shown in Table D2-27.

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, the PE sets both ESR_ELx.Isv, EX to 0.

**Note**

An implementation that always sets ISV to 0 and never sets EX is not compliant.

ESR_ELx.ISV is UNKNOWN if, in the active-not-pending state, either:

- The instruction stepped was an ERET or an ISB. In these cases, ESR_ELx.EX is set to 0.
- MDCR_EL2.TDE was set to 1 and either:
  - The instruction to be stepped generated a synchronous exception that was taken to Non-secure EL1. In this case, the instruction to be stepped never completed.
  - The PE took an asynchronous exception to Non-secure EL1 before it could execute the instruction to be stepped. In this case, the instruction to be stepped was never executed.

In both of these cases:

- If ESR_ELx.ISV is set to 1, then ESR_ELx.EX must be set to the correct value for the instruction.
- If ESR_ELx.ISV is set to 0, then ESR_ELx.EX must be set to zero.

---

<tr>
<td>The instruction to be stepped generated a synchronous exception that was taken to Non-secure EL1.</td>
<td>UNKNOWN</td>
<td>Set to the correct value for the instruction.</td>
</tr>
<tr>
<td>The PE took an asynchronous exception before it could execute the instruction to be stepped.</td>
<td>UNKNOWN</td>
<td>Set to the correct value for the instruction.</td>
</tr>
</tbody>
</table>

ESR_ELx.EX is **UNKNOWN** if the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code test.

--- **Note** ---

A Load-Exclusive instruction is any one of the following:
- In the A64 instruction set, any instruction that has a mnemonic starting with either LDX or LDAX.
- In the A32 and T32 instruction sets, any instruction that has a mnemonic starting with either LDREX or LDAEX.

---

**Preferred return address**

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

### D2.12.10 Additional considerations

This section contains the following:
- *Behavior when an ERET instruction is an illegal exception return.*
- *Behavior when the instruction stepped writes a misaligned PC value on page D2-2044.*
- *Stepping code that uses Exclusives monitors on page D2-2044.*
- *Synchronization and the software step state machine on page D2-2044.*

**Behavior when an ERET instruction is an illegal exception return**

If the conditions for entering the active-not-pending state in *Entering the active-not-pending state on page D2-2034* are met, but the PE executes an ERET instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the ERET, software step can advance from the inactive state to one of the active states. Consider the following case:

1. MDSCR_EL1.SS is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and MDCR_EL2.TDE is 0, MDSCR_EL1.KDE is 1, and PSTATE.D is 1.
   - PSTATE.D == 1 is the reason why software step is inactive, because PSTATE.D == 1 means that debug exceptions are disabled from the current Exception level.
2. The PE executes an ERET instruction.
3. The intended target of the ERET is EL2. This means that the ERET is an illegal exception return because the intended target is higher than the Exception level the ERET it is executed at. In this case, the ERET must target EL1 instead of EL2.

If SPSR_EL1.D is 0, then on the ERET PSTATE.D becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether SPSR_ELx.SS is 1 or 0:

- If SPSR_ELx.SS is 1, software step advances to the active-not-pending state.
  In this case, an Illegal Execution state exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution state exception instead of executing the instruction to be stepped.
- If SPSR_ELx.SS is 0, software step advances to the active-pending state.
  In this case, a Software Step exception and an Illegal Execution state exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets SPSR_ELx.IL to 1.

Note

Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895 shows the relative priorities of synchronous exceptions.

Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a PC alignment fault exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

| AArch64 | A PC alignment fault exception is generated. |
| AArch32 | The return from the Software Step exception forces the PC to the correct alignment, and no PC alignment fault exception is generated. |

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a PC alignment fault exception.

Stepping code that uses Exclusives monitors

The ARMv8-A architecture provides no mechanism for preserving the state of the Exclusives monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive instruction.

Debugger software can use this to detect the state of the Exclusives monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all Exclusives monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see Exception syndrome information and preferred return address on page D2-2041.

Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a System register.
- A direct write to a Special-purpose register.
- A write to an external debug register that affects the routing of debug exceptions.
Because the software step state machine indirectly reads these registers, it is not guaranteed to observe any new values until after a Context synchronization event has occurred.

In the time between a write to one of these registers and the next Context synchronization event, it is constrained unpredictable whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a Context synchronization event, the state machine must use the state of the PE after the write.

**Example D2-3**

1. Software changes MDSCR_EL1.SS from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A Context synchronization event occurs.

During step 2, it is constrained unpredictable whether software step remains in the inactive state, as if MDSCR_EL1.SS is 0, or enters the active-pending state because MDSCR_EL1.SS is 1. If it is in the:
   - Inactive state, then after the Context synchronization event, it must enter the active-pending state.
   - Active-pending state, the PE might take a Software Step exception before the Context synchronization event.

---

**Note**

A direct write to a Special-purpose register does not require explicit synchronization.

---

### D2.12.11 Pseudocode description of Software Step exceptions

**SSAdvance()** advances software step from the active-not-pending state to the active-pending state, by setting PSTATE.SS to 0. It is called on completing execution of each instruction.

**CheckSoftwareStep()** checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

**DebugExceptionReturnSS()** returns the value to write to PSTATE.SS on an exception return or an exit from Debug state. See *Entering the active-not-pending state on page D2-2034*.

These functions are defined in Chapter J1 *ARMv8 Pseudocode*. 
D2.13 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a Context synchronization event has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a Context synchronization event has occurred.

For any instructions executed between the time when the change is made and the time when the next Context synchronization event occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

---

Example D2-4

1. Software changes MDSCR_EL1.MDE from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A Context synchronization event occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

---

Example D2-5

1. Software unlocks the OS lock.
2. The PE executes some instructions.
3. A Context synchronization event occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

---

Note

- Some register updates are self-synchronizing. Others require an explicit Context synchronization event. For more information, see:
  - Accessing PSTATE fields on page D1-1866.
  - Synchronization requirements for AArch64 System registers on page D10-2349.
  - Synchronization of changes to the external debug registers on page H8-5818.
Chapter D3
The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

• About the memory system architecture on page D3-2048.
• Address space on page D3-2049.
• Mixed-endian support on page D3-2050.
• Cache support on page D3-2051.
• External aborts on page D3-2074.
• Memory barrier instructions on page D3-2076.
• Pseudocode description of general memory system instructions on page D3-2077.
D3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see Memory hierarchy on page B2-105.

D3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a Virtual Memory System Architecture (VMSA). Chapter D4 The AArch64 Virtual Memory System Architecture describes the AArch64 view of the VMSA.

D3.1.2 Memory attributes

Memory types and attributes on page B2-114 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table D3-1 shows the memory attributes that are visible at the system level.

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Shareability</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device¹</td>
<td>Outer Shareable</td>
<td>Non-cacheable.</td>
</tr>
<tr>
<td>Normal</td>
<td>One of:</td>
<td>One of:</td>
</tr>
<tr>
<td></td>
<td>• Non-shareable.</td>
<td>• Non-cacheable.</td>
</tr>
<tr>
<td></td>
<td>• Inner Shareable.</td>
<td>• Write-Through Cacheable.</td>
</tr>
<tr>
<td></td>
<td>• Outer Shareable.</td>
<td>• Write-Back Cacheable.</td>
</tr>
</tbody>
</table>

¹. Takes additional attributes, see Device memory on page B2-118.
². See also Cacheability, cache allocation hints, and cache transient hints on page D3-2054.

D3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of physical address (PA) sizes, and provides associated control and identification mechanisms. For more information, see Address size configuration on page D4-2097.

D3.2.1 Virtual address space overflow

When a PE performs a Simple sequential execution of instructions, it calculates:

(address_of_current_instruction) + (size_of_executed_instruction)

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows 0xFFFF FFFF FFFF FFFF, the program counter becomes UNKNOWN.

Note

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the 0xFFFF FFFF FFFF FFFF boundary when tagged addresses are not used, or the 0xFFFF FFFF FFFF FFFF boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN. When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.
D3.3 Mixed-endian support

A control bit, `SCTLR_EL1.E0E` is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. Table D3-2 shows the endianness of explicit data accesses and translation table walks.

### Table D3-2 Endianness support

<table>
<thead>
<tr>
<th>Exception level</th>
<th>Explicit data accesses</th>
<th>Stage 1 translation table walks</th>
<th>Stage 2 translation table walks</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td><code>SCTLR_EL1.E0E</code></td>
<td><code>SCTLR_EL1.EE</code></td>
<td><code>SCTLR_EL2.EE</code></td>
</tr>
<tr>
<td>EL1</td>
<td><code>SCTLR_EL1.EE</code></td>
<td><code>SCTLR_EL1.EE</code></td>
<td><code>SCTLR_EL2.EE</code></td>
</tr>
<tr>
<td>EL2</td>
<td><code>SCTLR_EL2.EE</code></td>
<td><code>SCTLR_EL2.EE</code></td>
<td>N/A</td>
</tr>
<tr>
<td>EL3</td>
<td><code>SCTLR_EL3.EE</code></td>
<td><code>SCTLR_EL3.EE</code></td>
<td>N/A</td>
</tr>
</tbody>
</table>

---

**Note**

`SCTLR_EL1.E0E` has no effect on the endianness of the `LDTR`, `LDTRH`, `LDTRSH`, and `LDTRSW` instructions, or on the endianness of the `STTR` and `STTRH` instructions, when these are executed at EL1.

AArch64 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - `SCTLR_ELx.EE` is RW and `SCTLR_EL1.E0E` is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - `SCTLR_ELx` is RES0 and `SCTLR_EL1.E0E` is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - `SCTLR_ELx` is RES1 and `SCTLR_EL1.E0E` is RW.
- All Exception levels support only little-endianness:
  - `SCTLR_ELx` is RES0 and `SCTLR_EL1.E0E` is RES0.
- All Exception levels support only big-endianness:
  - `SCTLR_ELx` is RES1 and `SCTLR_EL1.E0E` is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by `PSTATE.E`. For exception returns to AArch32 state, `PSTATE.E` is copied from `SPSR_ELx.E`. If the target Exception level supports only little-endian accesses, `SPSR_ELx.E` is RES0. If the target Exception level supports only big-endian accesses, `SPSR_ELx.E` is RES1. `PSTATE.E` is ignored in AArch64 state.

The `BigEndian()` function determines whether the current Exception level and Execution state are using big-endian data. This function is defined in Chapter J1 *ARMv8 Pseudocode*.

For more information about endianness in the ARM architecture see *Endian support on page B2-111*. 
D3.4 Cache support

This section describes the ARMv8 cache identification and control mechanisms, and the A64 cache maintenance instructions, in the following sections:

- General behavior of the caches.
- Cache identification on page D3-2052.
- Cacheability, cache allocation hints, and cache transient hints on page D3-2054.
- Enabling and disabling the caching of memory accesses on page D3-2055.
- Behavior of caches at reset on page D3-2057.
- Non-cacheable accesses and instruction caches on page D3-2057.
- About cache maintenance in AArch64 state on page D3-2058.
- A64 Cache maintenance instructions on page D3-2062
- Data cache zero instruction on page D3-2071.
- Cache lockdown on page D3-2072.
- System level caches on page D3-2073.
- Branch prediction on page D3-2073.

See also Caches in a VMSAv8-64 implementation on page D4-2221.

D3.4.1 General behavior of the caches

When a memory location has a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.

- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Note

For more information, see The interaction of cache lockdown with cache maintenance instructions on page D3-2072.

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.
• It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.

• It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
  — The translation regime at the current Exception level.
  — The translation regime at any higher Exception level.

• For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all masters in its shareability domain.

• Any memory location is not guaranteed to remain incoherent with the rest of memory.

• The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the Cache Write-back Granule. In some implementations the CTR_EL0 identifies the Cache Write-back Granule.

• The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer if it was previously visible to that observer.

Note

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR_EL1.{I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

D3.4.2 Cache identification

The ARMv8 cache identification registers describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes the cache maintenance instructions that:

• Affect the entire cache, for example IC IALLU.

• Operate by VA, for example IC IVAU.

• Operate by set/way, for example DC I5W.

The cache identification registers are:

• The Cache Type Register, CTR_EL0, that defines:
  — The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  — The minimum line length of any of the data or unified caches, affected by the data cache maintenance instruction.
  — The cache indexing and tagging policy of the Level 1 instruction cache.

Note

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see System level caches on page D3-2073.

• A single Cache Level ID Register, CLIDR_EL1, that defines:
  — The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
  — The Level of Coherence (LoC) for the caches. See Terms used in describing the cache maintenance instructions on page D3-2058 for the definition of LoC.
— The Level of Unification Uniprocessor (LoUU) for the caches. See Terms used in describing the cache maintenance instructions on page D3-2058 for the definition of LoUU.
— An optional ICB field to indicate the boundary between the caches used for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.

• A single Cache Size Selection Register, CSSELR_EL1, that selects the cache level and cache type of the current Cache Size Identification Register.

• For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, CCSIDR_EL1, that defines:
  — Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  — The number of sets, associativity and line length of the cache. See Terms used in describing the cache maintenance instructions on page D3-2058 for a definition of these terms.

______ Note ________

From ARMv8.3, multiple formats of the Cache Size Identification Register are supported. For more information, see Possible formats of the Cache Size Identification Register, CCSIDR_EL1.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.

2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.

3. For each cache identified at stage 2:
   • Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     — An instruction cache.
     — A data or unified cache.
   • Read the Cache Size Identification Register to find details of the cache.

Possible formats of the Cache Size Identification Register, CCSIDR_EL1

From ARMv8.3, the Cache Size Identification Register, CCSIDR_EL1 has two different formats available for defining the number of sets and associativity of the cache. For a definition of these terms, see Terms used in describing the cache maintenance instructions on page D3-2058.

When ARMv8.3-CCIDX is implemented:

• CCSIDR_EL1 is a 64-bit register.

• The length of the CCSIDR_EL1.Assoc field is 21 bits. This limits the associativity of the currently selected cache to $2^{21}$.

• The length of the CCSIDR_EL1.NumSets field is 24 bits. This limits the number of sets in the currently selected cache to $2^{24}$.

This is the 64-bit format of the Cache Size Identification Register.

When ARMv8.3-CCIDX is not implemented:

• CCSIDR_EL1 is a 32-bit register.

• The length of the CCSIDR_EL1.Assoc field is 10 bits. This limits the associativity of the currently selected cache to $2^{10}$. 

• The length of the CCSIDR_EL1.NumSets field is 15 bits. This limits the number of sets in the currently selected cache to $2^{15}$.

This is the 32-bit format of the Cache Size Identification Register.

When one of these formats is implemented, it is implemented across all the levels of caching.

### D3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in Memory types and attributes on page B2-114, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

In ARMv8, Cacheability attributes other than Non-cacheable can be complemented by a cache allocation hint. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a cache transient hint is supported, see Transient cacheability hint.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hit is supported the following cache allocation hints can be assigned:

**For read accesses:** Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

**For write accesses:** Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

---

**Note**

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.

- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.

- For VMSAv8-64 translation table walks, the TCR_ELx.{IRGN, ORGN} fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

**Transient cacheability hint**

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

---

**Note**

The architecture does not specify what is meant by a relatively short period.
The description of the AArch64 MAIR_EL1, MAIR_EL2, and MAIR_EL3 registers, and the AArch32 MAIR0, MAIR1, HMAIR0, and HMAIR1 registers, includes the assignment of the Transient hint in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

### D3.4.4 Enabling and disabling the caching of memory accesses

In ARMv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

**Note**

These Cacheability controls replace the cache enable controls provided in previous versions of the ARM architecture.

The Cacheability control fields and their effects are as follows:

**For the EL1&0 translation regime**

- When the value of SCTLR_EL1.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL1&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTLR_EL1.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR_EL2.CD is 1:
  - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL1&0 stage 2 translation tables are Non-cacheable.
- When the value of HCR_EL2.ID is 1:
  - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR_EL2.DC is 1, all Non-secure stage 1 translations and all accesses to the Non-secure EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of SCTLR_EL1.{I, C}. This applies to translations for both data and instruction accesses.

**Note**

- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in *Combining the stage 1 and stage 2 cacheability attributes for Normal memory* on page D4-2181.
- The SCTLR_EL1.{C, I} and HCR_EL2.DC fields have no effect on the EL2, EL2&0, and EL3 translation regimes.
- The HCR_EL2.{ID, CD} fields affect only stage 2 of the Non-secure EL1&0 translation regime.
- In Non-secure state, when EL2 is using AArch64 and EL1 is using AArch32, the HCR_EL2.{ID, CD, DC} controls apply as described here, but the EL1 controls are SCTLR.{C, I}.
For the EL2 translation regime

- When the value of SCTLR_EL2.C is 0:
  - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
  - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of SCTLR_EL2.I is 0:
  - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

--- Note ---

The SCTLR_EL2.{I, C} fields have no effect on the EL1&0 and EL3 translation regimes.

For the EL2&0 translation regime

- When the value of SCTLR_EL2.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL2&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTLR_EL2.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.

For the EL3 translation regime

- When the value of SCTLR_EL3.C is 0:
  - All data accesses to Normal memory using the EL3 translation regime are Non-cacheable.
  - All accesses to the EL3 translation tables are Non-cacheable.
- When the value of SCTLR_EL3.I is 0:
  - All instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

--- Note ---

The SCTLR_EL3.{I, C} fields have no effect on the EL1&0, EL2, and EL2&0 translation regimes.

In addition:

- For translation regimes other than the Non-secure EL1&0 translation regime, if the value of SCTLR_ELx.M is 0, indicating that stage 1 translations are disabled for that translation regime, then:
  - If the value of SCTLR_ELx.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
  - If the value of SCTLR_ELx.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

- For the Non-secure EL1&0 translation regime, if the value of SCTLR_EL1.M is 0, indicating that stage 1 translations are disabled for that translation regime, and the value of HCR_EL2.DC is 0:
  - If the value of SCTLR_EL1.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
  - If the value of SCTLR_EL1.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

The effect of SCTLR_ELx.C, HCR_EL2.DC and HCR_EL2.CD is reflected in the result of the address translation instructions in the PAR when these bits have an effect on the stages of translation being reported in the PAR.
D3 The AArch64 System Level Memory Model

D3.4 Cache support

Note

• In conjunction with the requirements in Non-cacheable accesses and instruction caches, the requirements in this section mean the architecturally required effect of SCTLR_ELx.I is limited to its effect on caching instruction accesses in unified caches.

• This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in Mismatched memory attributes on page B2-125 must be followed to manage the corresponding loss of coherency.

D3.4.5 Behavior of caches at reset

In ARMv8:

• All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.

• The Cacheability control fields described in Enabling and disabling the caching of memory accesses on page D3-2055 reset to values that force all memory locations to be treated as Non-cacheable.

Note

This applies only to the controls that apply to the Translation regime that is used by the Exception level and Security state entered on reset.

• An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.

• If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  — Provide a mechanism to ensure the correct initialization of the caches.
  — Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

• ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

See also TLB behavior at reset on page D4-2205.

D3.4.6 Non-cacheable accesses and instruction caches

In AArch64 state, instruction accesses to Non-cacheable Normal memory can be held in instruction caches. Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where System register Cacheability control fields force instruction accesses to memory to be Non-cacheable.

Therefore when using self-modified code in Non-cacheable space in a uniprocessor system, the following sequence is required:

; Enter this code with <Wt> containing the new 32-bit instruction
; to be held at a location pointed to by <Xn> in Normal Non-cacheable memory.
STR <Wt>, [Xn]
DSB ISH; Ensure visibility of the data stored
IC IVAU, [Xn]; Invalidate instruction cache by VA to PoU
DSB ISH; Ensure completion of the invalidations
ISB;
In a multiprocessor system, the IC IVAU is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence, but additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an ISB after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences.

Larger blocks of instructions can be modified using the IC IALLU instruction for a uniprocessor system, or a IC IALLUIS for a multiprocessor system.

**Note**

This section applies even when the Cacheability control fields force instruction accesses to memory in AArch64 state to be Non-cacheable, as described in *Enabling and disabling the caching of memory accesses on page D3-2055.*

### D3.4.7 About cache maintenance in AArch64 state

The following sections give general information about cache maintenance:

- **Terms used in describing the cache maintenance instructions.**
- **The ARMv8 abstraction of the cache hierarchy on page D3-2061.**

The following sections describe the A64 cache maintenance instructions:

- **The instruction cache maintenance instruction (IC) on page D3-2063.**
- **The data cache maintenance instruction (DC) on page D3-2063.**

**Note**

Some descriptions of the cache maintenance instructions refer to the cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR_EL1.{I, C} controls.

**Terms used in describing the cache maintenance instructions**

Cache maintenance instructions are defined to act on particular memory locations. Instruction scope can be defined:

- By the virtual address of the memory location to be maintained, referred to as operating by VA.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating by set/way.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- **Terminology for cache maintenance instructions operating by set/way.**
- **Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D3-2059.**

**Note**

There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see *The effects of disabling a stage of address translation on page D4-2136.*

**Terminology for cache maintenance instructions operating by set/way**

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

**Level**

The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the CLIDR_EL1.

In the ARM architecture, the lower numbered cache levels are those closest to the PE. See *Memory hierarchy on page B2-105.*
Set
Each level of a cache is split up into a number of sets. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.
In the ARM architecture, sets are numbered from 0.

Way
The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The way number specifies one of these locations.
In the ARM architecture, ways are numbered from 0.

Note
Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

Terminology for Clean, Invalidate, and Clean and Invalidate instructions
Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or stale, copy of the memory location that has been updated.

The Clean and Invalidate instructions address these two issues. The definitions of these instructions are:

Clean
A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

Invalidate
A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

Note
Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

Clean and Invalidate
A cache clean and invalidate instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
For instructions operating by VA, the following conceptual points are defined:

**Point of Coherency (PoC)**
The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

--- **Note** ---
The presence of system caches can affect the determination of the point of coherency as described in *System level caches* on page D3-2073.

**Point of Unification (PoU)**
The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.
The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:
1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

**Point of Persistence (PoP)**
The point in a memory system, if it exists, at or beyond the Point of Coherency, where a write to memory is maintained when system power is removed, and reliably recovered when power is restored to the affected locations in memory.

--- **Note** ---
*Such memory is sometimes called non-volatile memory. For example, the Storage-class memory shown in Figure B2-1 on page B2-105 could be used as target memory for this feature.*

--- **Note** ---
The PoP is relevant to the behavior of a PE only when ARMv8.2-DCPoP is implemented, see *DC CVAP*.

The following fields in the CLIDR_EL1 relate to the PoC and PoU:

**LoC, Level of Coherency**
This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:
* A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
* Level 4 cache is the first level that does not have to be maintained.
If the LoC field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.
If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

**LoUU, Level of Unification, uniprocessor**
This field defines the last level of data cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.
If the LoUU field value is 0x0, this means that no levels of data cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.
If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

**LoUIS, Level of Unification, Inner Shareable**

In any implementation:

- The LoUIS field defines the last level of data or unified cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is $0x0$, this means that no levels of data or unified cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

**The ARMv8 abstraction of the cache hierarchy**

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- **Cache maintenance instructions that operate by VA**
- **Cache maintenance instructions that operate by set/way**

**Cache maintenance instructions that operate by VA**

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being one of:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.
- When ARMv8.2-DCPoP is implemented, performed to the Point of Persistence.

See [Terms used in describing the cache maintenance instructions](#) on page D3-2058 for definitions of these terms, and for more information about possible meanings of VA.

**A64 Cache maintenance instructions** on page D3-2062 lists the VA-based maintenance instructions.

The CTR_EL0 holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of VAs, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR_EL0 defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

**Cache maintenance instructions that operate by set/way**

**A64 Cache maintenance instructions** on page D3-2062 lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.
**D3.4.8 A64 Cache maintenance instructions**

The A64 cache maintenance instructions are part of the A64 system instruction class in the register encoding space. For encoding details and other general information on these system instructions, see Section 3.16 of the System instructions, and Section 6.79 of the AArch32 cache and branch predictor maintenance instructions. Table D3-3 shows the AArch64 system instructions that perform instruction or data cache maintenance. Instructions that take an argument include Xt in the entry in the System instruction column.

---

**Note**

- In Table D3-3 the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.

- In general, the AArch32 instruction and data cache maintenance instructions provide equivalent functionality to the AArch64 cache maintenance instructions, see Section 3.16 of the System instructions, and Section 6.79 of the AArch32 cache and branch predictor maintenance instructions. However, the data cache clean to the Point of Persistence instruction, implemented when ARMv8.2-DCPoP is implemented, is supported in AArch64 state only.

a. Supported only when ARMv8.2-DCPoP is implemented.

A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores. The following subsections give more information about these instructions:

- *The instruction cache maintenance instruction (IC)* on page D3-2063.
- *The data cache maintenance instruction (DC)* on page D3-2063.
The instruction cache maintenance instruction (IC)

System instructions on page C3-164 describes the A64 assembly syntax for this instruction.

When an IC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:
- For an instruction executed at EL1, or at EL2 when HCR_EL2.E2H==1, the current ASID.
- The current Security state.
- Whether the instruction was executed at EL2, or in Non-secure EL1 state.
- For an instruction executed in Non-secure EL1 state, the current VMID.

That VA to PA translation might fault. However, for an instruction cache maintenance instruction that operates by VA:
- It is IMPLEMENTATION DEFINED whether the instruction can generate:
  - An Access flag fault.
  - A Translation fault.
- The instruction cannot generate a Permission fault, except for:
  - The possible generation of a Permission fault by the execution of an IC IVAU instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions on page D3-2065.
  - The possible Permission fault on a Stage 2 fault on a stage 1 translation table walk.

For more information about possible faults on a cache maintenance instruction that operates by VA see VMSAv8-64 memory aborts on page D4-2191.

See also Ordering and completion of data and instruction cache instructions on page D3-2069.

The data cache maintenance instruction (DC)

System instructions on page C3-164 describes the A64 assembly syntax for this instruction.

When a DC instruction requires a set/way/level argument this takes the form of a 64-bit register, the upper 32 bits of which are RES0.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-6427 or the instruction description.

When a DC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:
- For an instruction executed at EL1, or at EL2 when HCR_EL2.E2H==1, the current ASID.
- The current Security state.
• Whether the instruction was executed at EL2, or in Non-secure EL1 state.
• For an instruction executed in Non-secure EL1 state, the current VMID.

That VA to PA translation might fault. However, a data or unified cache maintenance instruction that operates by VA cannot generate a Permission fault except in the following cases:

• The possible generation of a Permission fault by:
  — The execution of a DC IVAC instruction when the specified address does not have write permission.
  — The execution of an enabled DC * instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions on page D3-2065.

The description of Permission faults includes possible constraints on the generation of Permission faults on cache maintenance by VA instructions.

• The possible Permission fault on a Stage 2 fault on a stage 1 translation table walk.

For more information about possible faults on a VA to PA translation see VMSAv8-64 memory aborts on page D4-2191.

When executed at EL1, a DC ISW instruction performs a clean and invalidate, meaning it performs the same maintenance as a DC CISW instruction, if all of the following apply:

• EL2 is implemented.
• Either:
  — The value of HCR_EL2.SWIO is 1, forcing a cache clean to perform a clean and invalidate.
  — The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.
• Either EL3 is not implemented, or EL3 is implemented and the value of SCR_EL3.NS is 1

When executed at EL1, a DC IVAC instruction performs a clean and invalidate, meaning it performs the same maintenance as a DC CVAC instruction, if all of the following apply:

• EL2 is implemented.
• The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.
• Either EL3 is not implemented, or EL3 is implemented and the value of SCR_EL3.NS is 1

—— Note ——
This also applies to the AArch32 cache maintenance instructions DCIMVAC and DCISW. See AArch32 data cache maintenance instructions (DC*) on page G3-4822.

—— Note ——
• Support for the Point of Persistence does not change the definition or behavior of the CLIDR_EL1 System register.

• Because a DSB SYS instruction will not complete until all previous DC CVAP instructions have completed, the following sequence can be used to ensure the completion of any store to the Point of Persistence, where the store might be to Non-cacheable memory:

  DMB  
  DC CVAP, Xt  
  DSB SYS  

  ; Note this can be any DMB that applies to both loads and stores

• If caches that are invisible to the programmer exist beyond the Point of Coherency but before the Point of Persistence and hold data that is marked as Non-cacheable, the DC CVAP operation causes the Non-cacheable locations to be cleaned from those caches.

If a memory fault that sets the FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.
Note

Despite its mnemonic, DC ZVA is not a cache maintenance instruction.

See also EL0 accessibility of cache maintenance instructions and Ordering and completion of data and instruction cache instructions on page D3-2069.

EL0 accessibility of cache maintenance instructions

The SCTLR_EL1.UCI bit enables EL0 access for the DC CVAU, DC CVAC, DC CVAP, DC CIVAC, and IC IVAU instructions. When EL0 use of these instructions is disabled because SCTLR_EL1.UCI == 0, executing one of these instructions at EL0 generates a trap to EL1, that is reported using EC = 0x18.

Note

DC CVAP is implemented only if ARMv8.2-DCPoP is implemented.

For these instructions read access permission is required. When the value of SCTLR_EL1.UCI is 1:

- For the DC CVAU, DC CVAC, DC CVAP, and DC CIVAC instructions, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, a Permission fault might be generated.
- For the IC IVAU instruction, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, it is IMPLEMENTATION DEFINED whether a Permission fault is generated.

For more information see the description of Permission faults. In the case of a DC * instruction executed at EL0 when the address specified cannot be read at EL0 the Permission fault is generated unless one of the permitted constraints described in that section applies and means the fault cannot be generated.

Software can read the CTR_EL0 to discover the stride needed for cache maintenance instructions. The SCTLR_EL1.UCT bit enables EL0 access to the CTR_EL0. When EL0 access to the Cache Type register is disabled, a register access instruction executed at EL0 is trapped to EL1 using EC = 0x18.

General requirements for the scope of maintenance instructions

The ARMv8 specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches on page D3-2051, Behavior of caches at reset on page D3-2057, and Preloading caches on page B2-108.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

Note

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

Effects of instructions that operate by VA to the PoC

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoC must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.
In all cases, for any affected PE, these instructions affect all data and unified caches to the PoC. Table D3-4 shows the scope of these Data and unified cache maintenance instructions.

**Effects of instructions that operate by VA to the PoP**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoP must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoP. Table D3-5 shows the scope of these Data and unified cache maintenance to the PoP instructions.

**Effects of instructions that operate by VA to the PoU**

For cache maintenance instructions that operate by VA to the PoU, Table D3-6 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.
Note
The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.

Effects of All and set/way maintenance instructions

The \texttt{IC IALLU} and \texttt{DC} set/way instructions apply only to the caches of the PE that performs the instruction.

The \texttt{IC IALLUIS} instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

Note
The possible presence of system caches, as described in System level caches on page D3-2073, means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.

Effects of virtualization and Security state on the cache maintenance instructions

Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space.

Table D3-7 shows the effects of virtualization and security on the cache maintenance instructions. In the table, the Specified entries are entries that the architecture requires the instruction to affect. The rules described in General behavior of the caches on page D3-2051 mean that an instruction might also affect other entries.

<table>

<td></td>
<td>• EL2, all instruction cache lines containing Non-secure entries.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• EL3 or Secure EL1, all instruction cache lines.</td>
</tr>
</tbody>
</table>
a. Dependencies on the VMID apply even when HCR_EL2.VM is set to 0. The architecture does not define a reset value for VTTBR_EL2.VMID, and therefore, in any implementation that includes EL2, the boot software executed when reset is deasserted must initialize VTTBR_EL2.VMID.

b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:
   • For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
   • For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in The interaction of cache lockdown with cache maintenance instructions on page D3-2072 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

• The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way instructions can, instead, perform a clean and invalidate by set/way.

• As described in The data cache maintenance instruction (DC) on page D3-2063, the AArch64 Data cache invalidate instructions, DC_INVAC and DC_INV, when executed at EL1 and EL0, and the AArch32 Data cache invalidate instructions DCIMVAC and DCISW, when executed at EL1, can be configured to perform a cache clean as well as a cache invalidation.

• When the value of HCR_EL2.FB is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch64, this applies to the TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, TLBI VAALE1, and IC IALLU instructions. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction, for example IC IALLU performs the invalidation that would be performed by IC IALLUIS.

For more information about the cache maintenance instructions, see About cache maintenance in AArch64 state on page D3-2058, A64 Cache maintenance instructions on page D3-2062, and Chapter D4 The AArch64 Virtual Memory System Architecture.

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instruction operates on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

• Whether the address accessed:
  — Is Normal memory or Device memory.
  — Has the Cacheable attribute or the Non-cacheable attribute.

• Any applicable domain control of the address accessed.

• The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.
Ordering and completion of data and instruction cache instructions

All data cache instructions, other than DC ZVA, that specify an address:

- Execute in program order relative to loads or stores that access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.

- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a DMB or DSB is executed between the instructions.

- Execute in program order relative to other data cache maintenance instructions, other than DC ZVA, that specify an address within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.

- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to other data cache maintenance instructions, other than DC ZVA, that specify an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

Note

- Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See Data and unified caches on page D4-2221.

- Data cache zero instruction on page D3-2071 describes the ordering and completion rules for Data Cache Zero.

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to data cache maintenance instructions that specify an address, other than Data Cache Zero, unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to loads or stores unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DSB is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction. See also the requirements for cache maintenance instructions in Completion and endpoint ordering on page B2-97.

In all cases, where the text in this section refers to a DMB or a DSB, this means a DMB or DSB whose required access type is both loads and stores.

Note

These ordering requirements are extended from the requirements in AArch32 state given in:

- Ordering of cache and branch predictor maintenance instructions on page G3-4829.
Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the CTR_EL0.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR_EL0.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

Since the set/way instructions are performed only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Since any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the line is not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

System level caches on page D3-2073 refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes that the current Cache Size Identification Register is in 32-bit format. For more information, see Possible formats of the Cache Size Identification Register, CCSIDR_EL1 on page D3-2053.

```
MRS  X0, CLIDR_EL1
AND  W3, W0, #0x07000000 // Get 2 x Level of Coherence
LSR  W3, W3, #23
CBZ  W3, Finished
MOV  W10, #0 // W10 = 2 x cache level
MOV  W8, #1  // W8 = constant 0b1
Loop1: ADD W2, W10, W10, LSR #1 // Calculate 3 x cache level
LSR W1, W0, W2  // extract 3-bit cache type for this level
AND W1, W1, #0x7 // No data or unified cache at this level
CMP W1, #2
B.LT Skip // Select this cache level
MSR CSSELR_EL1, X10 // Synchronize change of CSSELR
```

Note: The example code is for clearing the data or unified cache to the Point of Coherency. For more details on the possible formats of the Cache Size Identification Register, CCSIDR_EL1 on page D3-2053.
D3 The AArch64 System Level Memory Model

D3.4 Cache support

Similar approaches can be used for all cache maintenance instructions.

D3.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, `DC ZVA`, writes `0x00` to each byte of a block of `N` bytes, aligned in memory to `N` bytes in size, where:

- The block in memory is identified by the address supplied as an argument to the `DC ZVA` instruction. There are no alignment restrictions on this address.

Note: This means that each byte of the block of memory that includes the supplied address is set to zero.

- The `DCZID_EL0` register indicates the block size, `N` bytes, that is written with byte values of zero.

Software can restrict access to this instruction. See Configurable instruction enables and disables, and trap controls on page D1-1910 and the description of the `DC ZVA` instruction.

The `DC ZVA` instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See ISS encoding for an exception from a Data Abort on page D10-2460 for more information about the encoding of the associated ESR_ELx.ISS field.

- If the memory region being zeroed is any type of Device memory, then `DC ZVA` generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

Note: The architecture makes no statements about whether or not a `DC ZVA` instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.
D3.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, DC CSW.
  - Cache invalidate by set/way, DC ISW.
  - Cache clean and invalidate by set/way, DC CISW.
  - Instruction cache invalidate all, IC IALLU and IC IALLUIS.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose, see ISS encoding for an exception from a Data Abort on page D10-2460.

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, DC CVAC, DC CVAP, and DC CVAU.
- Cache invalidate by virtual address, DC IVAC.
- Cache clean and invalidate by virtual address, DC CIVAC.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose. See ESR_ELx on page K13-6595.

In an implementation that includes EL2, if HCR_EL2.TIDCP is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.
Note

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.

- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see Reserved encodings for IMPLEMENTATION DEFINED registers on page D9-2345.

D3.4.11 System level caches

The ARM Architecture defines a system cache as a cache that is not described in the PE Cache Identification registers, CCSIDR_EL1 and CLIDR_EL1, and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.

2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.

3. System caches which lie beyond the point of coherency and so are invisible to the software. The management of such caches is outside the scope of the architecture.

D3.4.12 Branch prediction

ARMv8 does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.
D3.5 External aborts

The ARM architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

An External abort is one of the following:
- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception terminology on page D1-1851.

The RAS Extension provides a more granular taxonomy of aborts. When the RAS Extension is not implemented, the ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

VMSAv8-64 permits External aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported. Asynchronous aborts are taken as SError interrupt exceptions. See Asynchronous exception types, routing, masking and priorities on page D1-1902.

Synchronous External aborts are reported using the Instruction Abort and Data Abort exceptions. See Synchronous exception types, routing and priorities on page D1-1894.

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running, ARM recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:
- External abort on an instruction fetch.
- External abort on data read or write.
- Provision for the classification of External aborts on page D3-2075.
- Parity or ECC error reporting, RAS Extension not implemented on page D3-2075.

D3.5.1 External abort on an instruction fetch

An External abort on an instruction fetch can be either synchronous or asynchronous.

A synchronous External abort on an instruction fetch is taken precisely using the Instruction Abort exception.

An implementation can report the External abort asynchronously from the instruction that it applies to. In such an implementation the abort is taken using the SError interrupt exception.

D3.5.2 External abort on data read or write

Externally-generated errors that occur during a data read or write can be either synchronous or asynchronous.

A synchronous External abort on a data read or write is taken precisely using the Data Abort exception.

An implementation can report the External abort asynchronously from the instruction that generated the access. In such an implementation the abort is taken using the SError interrupt exception.

The effect of a failed memory access is described in Effect of Data Aborts on page D1-1899.
D3.5.3 Provision for the classification of External aborts

In AArch64 state, an implementation can use ESR_ELx.EA, ISS[9], to provide more information about synchronous External aborts. For all synchronous aborts other than synchronous External aborts, ESR_ELx.EA, ISS[9], returns a value of 0.

If the RAS Extension is implemented:
• The ESR_ELx.SET field provides information about the state of the PE following a synchronous External abort.
• The ESR_ELx.AET field might contain more information following an asynchronous abort taken as an SError interrupt.
• The implementation might define error record registers.

For more information, see:
• ISS encoding for an exception from an Instruction Abort on page D10-2457.
• ISS encoding for an exception from a Data Abort on page D10-2460.
• ISS encoding for an SError interrupt on page D10-2466.
• ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

D3.5.4 Parity or ECC error reporting, RAS Extension not implemented

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-1876. However, when parity or ECC error reporting is implemented, it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.
D3.6 Memory barrier instructions

Memory barriers on page B2-98 describes the memory barrier instructions. This section describes the system level controls of those instructions.

D3.6.1 EL2 control of the shareability of data barrier instructions executed at Non-secure EL0 or EL1

In an implementation that includes EL2 and supports shareability limitations on the data barrier instructions, the HCR_EL2.BSU field can modify the required shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. Table D3-8 shows the encoding of this field.

Table D3-8 EL2 control of shareability of barrier instructions executed at Non-secure EL0 or EL1

<table>
<thead>
<tr>
<th>HCR_EL2.BSU</th>
<th>Minimum shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, shareability is as specified by the instruction</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

For an instruction executed at EL0 or EL1 in Non-secure state, Table D3-9 shows how the HCR_EL2.BSU is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction.

Table D3-9 Effect of HCR_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL0

<table>

D3.7 Pseudocode description of general memory system instructions

This section lists the pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access.
- Aligned memory access on page D3-2078.
- Unaligned memory access on page D3-2078.
- Exclusives monitors operations on page D3-2078.
- Access permission checking on page D3-2079.
- Abort exceptions on page D3-2079.
- Memory barriers on page D3-2079.

D3.7.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the `AddressDescriptor` type.
- Full address, defined by the `FullAddress` type.
- Memory attributes, defined by the `MemoryAttributes` type.
- Memory type, defined by the `MemType` enumeration.
- Device memory type, defined by the `DeviceType` enumeration.
- Normal memory attributes, defined by the `MemAttrHints` type.
- Cacheability attributes, defined by the `MemAttr_NC`, `MemAttr_WT`, and `MemAttr_WB` constants.
- Allocation hints, defined by the `MemHint_No`, `MemHint_WA`, `MemHint_RA`, and `MemHint_RW_A` constants.
- Access permissions, defined by the `Permissions` type.

These types are defined in Chapter J1 ARMv8 Pseudocode.

D3.7.2 Basic memory access

The two forms of the `_Mem[]` accessor, non-assignment (memory read) `_Mem[]` and assignment (memory write) `_Mem[]`, are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The functions address the array using `desc.paddress`, that supplies:

- The physical address.
- An NS bit that selects between the Secure and Non-secure parts of the array.

The attributes in `desc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes on page B2-114, Ordering and observability on page B2-93, and Atomicity in the ARM architecture on page B2-88.

An additional parameter to the `_Mem[]` accessor defines the access type, for example normal, exclusive, ordered, or streaming, and whether the access is made as part of a translation table walk.

The actual implemented array of physical memory might be smaller than the maximum size permitted by the architecture. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to External aborts or a System Error.
Note

The permitted physical memory size is:

- \(2^{52}\) bytes in an implementation that includes ARMv8.2-LPA. However, only \(2^{48}\) bytes are accessible using the 4KB or 16KB translation granule.
- \(2^{48}\) bytes otherwise.

\(\text{PAMax}()\) returns the IMPLEMENTATION DEFINED size of the physical address.

D3.7.3 Aligned memory access

The two \(\text{MemSingle}[]\) accessors, non-assignment (memory read) \(\text{AArch64.MemSingle}[]\) and assignment (memory write) \(\text{AArch64.MemSingle}[]\), make atomic, little-endian accesses of size \(\text{size}\) bytes. These functions are defined in Chapter J1 ARMv8 Pseudocode.

D3.7.4 Unaligned memory access

The two \(\text{Mem}[]\) accessors, Non-assignment (memory read) \(\text{Mem}[]\) and Assignment (memory write) \(\text{Mem}[]\), make accesses of the required type. If an access is not architecturally defined to be atomic, \(\text{Mem}[]\) synthesizes accesses from multiple calls to \(\text{AArch64.MemSingle}[]\). It also reverses the byte order if the access is big-endian.

The \(\text{AArch64.CheckAlignment}()\) function checks the alignment of memory accesses.

D3.7.5 Exclusives monitors operations

The \(\text{AArch64.SetExclusiveMonitors}()\) function sets the Exclusives monitors for a block of bytes, the size of which is determined by \(\text{size}\), at the virtual address defined by \(\text{address}\).

The \(\text{AArch64.ExclusiveMonitorsPass}()\) function checks whether the Exclusives monitors are set to include the location of a number of bytes specified by \(\text{size}\), at the virtual address defined by \(\text{address}\). The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to \(\text{AArch64.SetExclusiveMonitors}()\).

The \(\text{ExclusiveMonitorsStatus}()\) function returns 0 if the previous atomic write was to the same physical memory locations selected by \(\text{AArch64.ExclusiveMonitorsPass}()\) and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The \(\text{MarkExclusiveGlobal}()\) procedure takes as arguments a FullAddress \(\text{paddress}\), the PE identifier \(\text{processorid}\) and the size of the transfer. The procedure records that the PE \(\text{processorid}\) has requested exclusive access covering at least size bytes from address \(\text{paddress}\). The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The \(\text{MarkExclusiveLocal}()\) procedure takes as arguments a FullAddress \(\text{paddress}\), the PE identifier \(\text{processorid}\) and the size of the transfer. The procedure records in a local record that PE \(\text{processorid}\) has requested exclusive access to an address covering at least size bytes from address \(\text{paddress}\). The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a \(\text{MarkExclusiveGlobal}()\) using the same parameters.

The \(\text{IsExclusiveGlobal}()\) function takes as arguments a FullAddress \(\text{paddress}\), the PE identifier \(\text{processorid}\) and the size of the transfer. The function returns TRUE if the PE \(\text{processorid}\) has marked in a global record an address range as exclusive access requested that covers at least size bytes from address \(\text{paddress}\). It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, \(\text{IsExclusiveGlobal}()\) returns FALSE.
The `IsExclusiveLocal()` function takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked an address range as exclusive access requested that covers at least the size bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether this function returns `TRUE` or `FALSE` if the address marked as exclusive access requested does not cover all of size bytes from address `paddress`. If no address is marked as exclusive access requested, then this function returns `FALSE`. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which any size bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any address has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

These functions are defined in Chapter J1 *ARMv8 Pseudocode*.

### D3.7.6 Access permission checking

The function `AArch64.CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors. It returns the result of the call to `AArch64.NoFault()`.

These functions are defined in Chapter J1 *ARMv8 Pseudocode*.

The interpretation of access permission is shown in *Memory access control* on page D4-2155.

### D3.7.7 Abort exceptions

The function `AArch64.Abort()` generates either a Data Abort or an Instruction Abort exception by calling `AArch64.DataAbort()` or `AArch64.InstructionAbort()`. It also can generate a debug exception for debug related faults, see Chapter D2 *AArch64 Self-hosted Debug*.

The function `AArch64.DataAbort()` generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx. See *ISS encoding for an exception from a Data Abort* on page D10-2460. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.DataAbort()` also sets the FAR to the VA of the abort.

The function `AArch64.InstructionAbort()` generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx, see *ISS encoding for an exception from an Instruction Abort* on page D10-2457. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.InstructionAbort()` also sets the FAR to the VA of the abort.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. *Pseudocode description of the MMU faults* on page D4-2200 provides a number of wrappers to generate `FaultRecord`s.

The function `AArch64.NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

### D3.7.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

The `IsExclusiveLocal()` function takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked an address range as exclusive access requested that covers at least the size bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether this function returns `TRUE` or `FALSE` if the address marked as exclusive access requested does not cover all of size bytes from address `paddress`. If no address is marked as exclusive access requested, then this function returns `FALSE`. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of size bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of size bytes starting from `paddress` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

These functions are defined in Chapter J1 *ARMv8 Pseudocode*.
These enumerations define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures `DataMemoryBarrier`, `DataSynchronizationBarrier`, and `InstructionSynchronizationBarrier` perform the memory barriers.
Chapter D4
The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 Virtual Memory System Architecture (VMSAv8-64), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state. It contains the following sections:

- About the Virtual Memory System Architecture (VMSA) on page D4-2082.
- The VMSAv8-64 address translation system on page D4-2091.
- VMSAv8-64 translation table format descriptors on page D4-2143.
- Memory access control on page D4-2155.
- Memory region attributes on page D4-2174.
- Virtualization Host Extensions on page D4-2183.
- VMSAv8-64 memory aborts on page D4-2191.
- Nested virtualization on page D4-2188.
- Translation Lookaside Buffers (TLBs) on page D4-2201.
- TLB maintenance requirements and the TLB maintenance instructions on page D4-2207.
- Caches in a VMSAv8-64 implementation on page D4-2221.
This chapter describes the ARMv8 Virtual Memory System Architecture (VMSA), and in particular how it applies to a PE that is executing in AArch64 state. In this state the PE is using VMSAv8-64, as defined in ARMv8 VMSA naming. See The ARMv8 VMSA when some Exception levels are using AArch32 for information about the VMSA in other contexts.

A VMSA provides a Memory Management Unit (MMU), that controls address translation, access permissions, and memory attribute determination and checking, for memory accesses made by the PE. The process of address translation maps the virtual addresses (VAs) used by the PE onto the physical addresses (PAs) of the physical memory system. The mapping of a VA to a PA requires either a single stage of translation, or two sequential stages of translation.

The translations are defined independently for different Exception levels and Security states, as described in The VMSAv8-64 address translation system on page D4-2091.

VMSAv8-64 supports tagging of VAs, as described in Address tagging in AArch64 state on page D4-2084. As that section describes, this address tagging has no effect on the address translation process.

The remainder of this chapter gives a full description of VMSAv8-64 for an implementation that includes all of the Exception levels. The implemented Exception levels and the resulting translation stages and regimes on page D4-2095 describes the differences in the VMSA if some Exception levels are not implemented.

The following sections give more information about the VMSA:

- ARMv8 VMSA naming.
- The ARMv8 VMSA when some Exception levels are using AArch32.
- VMSA address types and address spaces on page D4-2083.
- Address tagging in AArch64 state on page D4-2084.
- Pointer authentication in AArch64 state on page D4-2086.

### D4.1.1 ARMv8 VMSA naming

The ARMv8 VMSA naming model reflects the possible stages of address translation, as follows:

- **VMSAv8** The overall translation scheme, within which an address translation has one or two stages.
- **VMSAv8-32** The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch32. VMSAv8-32 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch32.
- **VMSAv8-64** The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch64. VMSAv8-64 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch64.

### D4.1.2 The ARMv8 VMSA when some Exception levels are using AArch32

As stated at the start of the chapter, this chapter describes VMSAv8-64, the ARMv8 VMSA that applies to an Exception level that is using AArch64. However, when a higher Exception level is using AArch64, and therefore using VMSAv8-64, lower Exception levels can be using AArch32. Chapter G4 The AArch32 Virtual Memory System Architecture describes VMSAv8-32, meaning it describes:

- The translation stages and translation regimes when EL3 is using AArch32.
- Any stages of address translation that are using VMSAv8-32 when EL3 is using AArch64.

However, a PE can be executing at EL0 using AArch32 when the next higher Exception level is using AArch64, for example when EL0 is using AArch32 and EL1 is using AArch64. When this is the case execution at EL0 uses a VMSAv8-64 translation regime as described in Constraints on accesses from EL0 when EL0 is using AArch32 on page D4-2093.
D4.1.3 VMSA address types and address spaces

A description of the VMSA refers to the following address types.

--- Note ---

These descriptions relate to the VMSAv8 description and therefore give more detail than the generic definitions given in the glossary.

---

Virtual address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

--- Note ---

This means that an address held in the PC, LR, SP, or an ELR, is a VA.

---

In AArch64 state, the VA has a maximum address width of either 48 bits or, when ARMv8.2-LVA is implemented and the 64KB translation granule is used, 52 bits. As About address translation and supported input address ranges on page D4-2094 describes, a stage of address translation can support one or two VA ranges:

Translation stage can support only a single VA range

For a translation stage that supports a single VA range, a 48-bit VA width gives a VA range of 0x0000000000000000 to 0x0000FFFFFFFFFFFF.

If ARMv8.2-LVA is implemented and the 64KB translation granule is used, for a translation regime that supports a single VA range, the 52-bit VA width gives a VA range of 0x0000000000000000 to 0x000FFFFFFFFFFFF.

Translation stage can support two VA ranges

For a translation stage that supports two VA subranges, one at the bottom of the full 64-bit address range, and one at the top, as follows:

- The bottom VA range runs up from address 0x0000000000000000. With a maximum VA width of 48 bits this gives a VA range of 0x0000000000000000 to 0x0000FFFFFFFFFFFF.
  With a maximum VA width of 52 bits this gives a VA range of 0x0000000000000000 to 0x000xFFFFFFFFFFFF.
- The top VA subrange runs up to address 0xFFFFFFFFFFFFFFFF. With a maximum VA width of 48 bits this gives a VA range of 0xFFFFFFFF000000000000 to 0xFFFFFFFFFFFFFFFF.
  With a maximum VA width of 52 bits this gives a VA range of 0xFFFFFFFF000000000000 to 0xFFFFFFFFFFFFFFFF.

Reducing the VA width for this subrange increases the bottom address of the range.

--- Note ---

- When ARMv8.1-VHE is not implemented, the only translation stage that can support two VA ranges is stage 1 of the EL1&0 translation regime.
- When ARMv8.1-VHE is implemented and the value of HCR_EL2 is 1, stage 1 of the EL2, or EL2&0, translation regime also can support two VA ranges.

A 48-bit VA range corresponds to an address space of 256TB. A 52-bit VA range corresponds to an address space of 4PB.

Each translation regime that takes a VA as an input address can be configured to support fewer than the maximum number of bits of VA space, see Address size configuration on page D4-2097.
Intermediate physical address (IPA)

In a translation regime that provides two stages of address translation, the IPA is:

- The OA from the stage 1 translation.
- The IA for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA. Alternatively, the translation regime can be considered as having no concept of IPAs.

For more information about maximum address widths, see Address size configuration on page D4-2097.

Physical address (PA)

The address of a location in a physical memory map. That is, an output address from the PE to the memory system.

The EL3 and Secure EL1 Exception levels provide independent definitions of the PA spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:

- A VA accessed in Secure state can be translated to either the Secure or the Non-secure PA space.
- When in Non-secure state, a VA is always mapped to the Non-secure PA space.

For more information about maximum address widths, see Address size configuration on page D4-2097.

D4.1.4 Address tagging in AArch64 state

In AArch64 state, the ARMv8 architecture supports the tagging of addresses. In these cases the top eight bits of the VA are ignored when determining:

- If the translation system is enabled, whether the address is out of range and therefore causes a Translation fault.
- If the translation system is not enabled, whether the address is out of range and therefore causes an Address size fault.
- Whether the address requires invalidation when performing a TLB invalidation instruction by address.

The use of address tags is controlled as follows:

For addresses when stage 1 translation can support two VA ranges

The value of bit[55] of the VA determines the register bit that controls the use of address tags, as follows:

\[
\begin{align*}
\text{VA}[55] &= 0 & \text{TCR\_ELx.TBI0} & \text{determines whether address tags are used. If stage 1 translation is enabled, TTBR0\_ELx holds the base address of the translation tables used to translate the address.} \\
\text{VA}[55] &= 1 & \text{TCR\_ELx.TBI1} & \text{determines whether address tags are used. If stage 1 translation is enabled, TTBR1\_ELx holds the base address of the translation tables used to translate the address.}
\end{align*}
\]

For addresses when stage 1 translation supports only a single VA range

- TCR\_ELx.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0\_ELx holds the base address of the translation tables used to translate the address.

Note

The TCR\_ELx.TBI\{n\} bit determines whether address tags are used regardless of whether the corresponding translation regime is enabled.

Note

When ARMv8.3-PAuth is implemented, TBID\{n\} bits are added to TCR\_ELx registers.

When a TCR\_ELx.TBI\{n\} bit enables the use of address tagging, the corresponding TBID\{n\} bit determines whether address tagging is used for both instruction and data addresses, or only for data addresses.
The bits added are:

- **TCR_EL1.\{TBID1, TBID0\}**.
- If stage 1 of the EL2 or EL2&0 translation regime supports two VA ranges, **TCR_EL2.\{TBID1, TBID0\}**. Otherwise, **TCR_EL2.TBID**.
- **TCR_EL3.TBID**.

--- **Note**

Restricting address tagging to data addresses means instruction addresses can use larger Pointer authentication code fields. See *Pointer authentication in AArch64 state* on page D4-2086.

An address tag enable bit also has an effect on the PC value in the following cases:

- On taking an exception to the controlled Exception level, regardless of whether this is also the Exception level from which the exception was taken.
- Any branch within the controlled Exception level, unless that branch generates an Illegal exception return.
- On performing an exception return that is not an Illegal exception return to the controlled Exception level, regardless of whether this is also the Exception level from which the exception return was performed.

--- **Note**

On an Illegal exception return, bits[63:32] of the PC become **UNKNOWN**.

- Exiting from debug state to the controlled Exception level.

--- **Note**

As an example of what is meant by the **controlled Exception level**, **TCR_EL3.TBI** controls this effect for:

- A branch or procedure return within EL3.
- Taking an exception to EL3.
- Performing an exception return or a debug state exit to EL3.

The effect of the controlling **TBI{n}** bit is:

**For a translation regime where stage 1 translation can support two VA ranges**

If the controlling TBI{n} bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be a sign-extension of bit[55] of that address.

**For a translation regime where stage 1 translation supports only a single VA range**

If the controlling TBI bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be 0x00.

However, when **ARMv8.3-PAuth** is implemented and the value of a **TCR_ELx.TBID{n}** field is 1, the **Effective value** of the corresponding **TCR_ELx.TBI{n}** field is 0 for any of:

- A branch or procedure return within an Exception level.
- Taking an exception to an Exception level.
- Exception return to an Exception level.
- Exit from Debug state to an Exception level.

The **AddrTop()** pseudocode function shows the algorithm determining the most significant bit of the VA, and therefore whether the VA is using tagging. For a translation regime where the stage 1 translation supports two VA ranges, this pseudocode includes the selection between **TTBR0_ELx** and **TTBR1_ELx** described in *Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported* on page D4-2128.
The required behavior prevents a tagged address being propagated to the program counter.

When address tagging is enabled for an address that causes a Data Abort or a Watchpoint, the address tag is included in the VA returned in the FAR.

### D4.1.5 Pointer authentication in AArch64 state

**ARMv8.3-PAuth** adds functionality that supports the authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load. This functionality is supported only in AArch64 state.

For pointer authentication, the new functionality provides:

- An instruction that inserts a Pointer Authentication Code (PAC) into the upper bits of a register. The bits used are the extension bits that do not hold valid address bits. The inserted PAC value is calculated from the value of the register and one other 64-bit value.

- An instruction that extracts the PAC from the upper bits of a register, and checks that the value is correct, based on the value of the register and one other 64-bit value, and:
  - If the value is correct, replaces the PAC with the extension bits.
  - Otherwise, replaces the PAC with the extension bits, except that two bits of the extension are set to a fixed unique number. This means that, if the register is used as the target of an indirect branch, execution branches to an address that generates a Translation fault because the VA is not mapped.

- An instruction that removes the PAC, replacing it with the extension bits, without any verification.

Multiple versions of these instructions are provided to support different use cases. These include instructions that combine a pointer authentication operation with another operation. Pointer authentication instructions on page C3-166 summarizes these instructions.

In addition, **ARMv8.3-PAuth** provides a generic authentication instruction, PACGA, that generates a 32-bit PAC from two 64-bit values.

---

**Note**

The PACGA instruction can be used to provide protection for small blocks of memory. Instructions can be chained to allow protection of an arbitrary-sized block.

---

For the Pointer authentication instructions, it is IMPLEMENTATION DEFINED whether PACs are generated using:

- The QARMA algorithm, see The QARMA Block Cipher Family. When this is the case, the value of ID_AA64ISAR1_EL1.APA is 0b0001.

- An IMPLEMENTATION DEFINED algorithm. When this is the case, the value of ID_AA64ISAR1_EL1.API is 0b0001.

Similarly, for the PACGA instruction, it is IMPLEMENTATION DEFINED whether PACs are generated using:

- The QARMA algorithm, see The QARMA Block Cipher Family. When this is the case, the value of ID_AA64ISAR1_EL1.GPA is 0b0001.

- An IMPLEMENTATION DEFINED algorithm. When this is the case, the value of ID_AA64ISAR1_EL1.GPI is 0b0001.

The pseudocode descriptions of the operation of these instructions describe the use of the QARMA algorithm. When an IMPLEMENTATION DEFINED algorithm is used the ComputePAC() function:

- Must have the same arguments as the function defined in this Manual.

- For a set of arguments passed to the function, must give the same result for all PEs that a thread of execution could migrate between.
ARMv8.3-PAuth is implemented if the value of at least one of ID_AAA64ISAR1_EL1.{APA, API, GPA, GPI} is 0b0001.

--- Note ---

Pointer authentication functionality is useful only when address translation is enabled. However, this functionality is the same whether address translation is enabled or disabled.

---

The following sections give more information about the ARMv8.3-PAuth functionality:

- Supported PAC field and relation to the use of address tagging.
- Keys for PAC generation and verification.
- System register control of pointer authentication on page D4-2088.

**Supported PAC field and relation to the use of address tagging**

As stated earlier in this section, the PAC is held in the extension bits of a register, that do not hold valid address bits. However, as described in Address tagging in AArch64 state on page D4-2084, when address tagging is used the tag is held in Xn[63:56]. Therefore, when Xn is a 64-bit register holding an address:

When address tagging is used

The PAC field is Xn[54:bottom_PAC_bit].

When address tagging is not used

The PAC field is Xn[63:56, 54:bottom_PAC_bit].

In the PAC field definitions, bottom_PAC_bit == 64 - TCR_ELx.TnSZ,

--- Note ---

Xn[55] determines whether the address lies in the upper or lower address range for the purpose of determining whether address tagging is used, see Address tagging in AArch64 state on page D4-2084. The value of Xn[55] is the value of n in TnSZ. Therefore, it also determines whether Xn[63:56] are part of the PAC field, and which of TCR_ELx.{T0SZ, T1SZ} determines the value of bottom_PAC_bit.

---

If the value of TCR_ELx.TnSZ is outside its permitted range then it is CONSTRAINED UNPREDICTABLE whether the value used to determine bottom_PAC_bit is the programmed value of the field, or is forced to the maximum or minimum permitted value of the field. However, if the PE treats an out of range TnSZ value as the maximum or minimum permitted value of the field for all purposes except reading the value of the field then that behavior also applies to determining bottom_PAC_bit.

ARMv8.3-PAuth adds a new control to TCR_ELx, that disables the use of address tagging for instruction addresses, see Address tagging in AArch64 state on page D4-2084.

--- Note ---

This control means software can use larger PAC field for instruction addresses, while using tagging and the smaller PAC field for data addresses.

**Keys for PAC generation and verification**

For pointer authentication, two 128-bit keys are provided for each of instruction addresses and data addresses, and a fifth 128-bit key is provided for the generic authentication instruction, as follows:

**Keys for instruction address PACs**

APIAKey_EL1

The concatenation of the register values APIAKeyHi_EL1:APIAKeyLo_EL1.

APIBKey_EL1

The concatenation of the register values APIBKeyHi_EL1:APIBKeyLo_EL1.
Keys for data address PACs

APDAKey_EL1  
The concatenation of the register values APDAKeyHi_EL1:APDAKeyLo_EL1.

APDBKey_EL1  
The concatenation of the register values APDBKeyHi_EL1:APDBKeyLo_EL1.

Key for generic authentication

APGAKey_EL1  
The concatenation of the register values APGAKeyHi_EL1:APGAKeyLo_EL1.

Note

Keys are not banked by Exception level. ARM expects software to switch the keys between Exception levels, typically by swapping the values with zero so that the current key values are not present in memory.

System register control of pointer authentication

ARMv8.3-PAuth adds controls to the SCTLR_ELx registers that enable generation and validation of PACs for data and instruction addresses. Formally, the definition of these fields is that when the functionality is disabled the AddPAC<|D><A|B>() and Auth<|D><A|B>() pseudocode functions return the value of the first parameter passed to them. This means:

• Except for PACGA, the instructions listed in Table C3-11 on page C3-166, that add a PAC to an address in a register, execute as NOPs.
• The instructions listed in Table C3-12 on page C3-167, that authenticate a pointer, execute as NOPs.
• For the Combined instructions listed in Table C3-14 on page C3-168, the Auth<|D><A|B>() function has no effect on the operation of the instruction, which operates as the equivalent non-Authenticate pointer instruction. This means that, for example:
  — A RETAA instruction operates as a RET instruction.
  — A LDRRA Xt, [Xn, #<imm10>]| instruction operates as a LDR Xt, [Xn, #<imm10>:000]| instruction.

These controls do not affect the PACGA and XPAC* instructions, that are always enabled.

The controls added to the SCTLR_ELx registers are:

EnIA  Controls instructions that apply to PACs for instruction addresses that are generated using the APIAKey_EL1 key.

EnIB  Controls instructions that apply to PACs for instruction addresses that are generated using the APIBKey_EL1 key.

EnDA  Controls instructions that apply to PACs for data addresses that are generated using the APDAKey_EL1 key.

EnDB  Controls instructions that apply to PACs for data addresses that are generated using the APDBKey_EL1 key.

See the SCTLR_ELx.{EnIA, EnIB, EnDA, EnDB} field descriptions for more information.

Note

These fields are RES0 in versions of the architecture before ARMv8.3, and therefore should be written as 0 by legacy software.
ARMv8.3-PAuth also adds System register controls that trap accesses to Pointer authentication functionality. These controls are:

**HCR_EL2.APK**

Traps to EL2 any access to a PAC key register from Non-secure EL1. Applies to accesses from Non-secure EL1 to APDAKeyHi_EL1, APDAKeyLo_EL1, APDBKeyHi_EL1, APDBKeyLo_EL1, APIAKeyHi_EL1, APIAKeyLo_EL1, APIBKeyHi_EL1, APIBKeyLo_EL1, APGAKeyHi_EL1, and APGAKeyLo_EL1.

These traps are reported in ESR_EL2 using EC code 0x18.

If EL2 is not implemented, the system behaves as if the value of HCR_EL2.APK is 1.

**HCR_EL2.API**

Traps to EL2 any use of an enabled Pointer authentication instruction:
- At Non-secure EL1.
- If HCR_EL2.TGE==0 or HCR_EL2.E2H==0, at Non-secure EL0.

These traps are reported in ESR_EL2 using EC code 0x9.

For this description:
- The Pointer authentication instructions are all of the instructions summarized in Pointer authentication instructions on page C3-166.
- Of those instructions:
  - The PACGA and XPAC* instructions are always enabled.
  - Any other instruction is enabled only if the value of the corresponding SCTLR_ELx.{EnIA, EnIB, EnDA, EnDB} field is 1.

If EL2 is not implemented, the system behaves as if the value of HCR_EL2.API is 1.

**SCR_EL3.APK**

Traps to EL3 any access to a PAC key register from EL2 or EL1. Applies to accesses from Secure EL1, Non-secure EL1, and EL2 to APDAKeyHi_EL1, APDAKeyLo_EL1, APDBKeyHi_EL1, APDBKeyLo_EL1, APIAKeyHi_EL1, APIAKeyLo_EL1, APIBKeyHi_EL1, APIBKeyLo_EL1, APGAKeyHi_EL1, and APGAKeyLo_EL1.

These traps are reported in ESR_EL3 using EC code 0x18.

If EL3 is not implemented, the system behaves as if the value of SCR_EL3.APK is 1.

**SCR_EL3.API**

Traps to EL3 any use of an enabled Pointer authentication instruction:
- At EL2.
- At Secure or Non-secure EL1.
- At Secure or Non-secure EL0.

These traps are reported in ESR_EL3 using EC code 0x9.

For this description:
- The Pointer authentication instructions are all of the instructions summarized in Pointer authentication instructions on page C3-166.
- Of those instructions:
  - The PACGA and XPAC* instructions are always enabled.
  - Any other instruction is enabled only if the value of the corresponding SCTLR_ELx.{EnIA, EnIB, EnDA, EnDB} field is 1.

If EL3 is not implemented, the system behaves as if the value of SCR_EL3.API is 1.

For more information about these controls see the HCR_EL2.APK, API and SCR_EL3.APK, API field descriptions.
These fields are RES0 in versions of the architecture before ARMv8.3, and therefore should be written as 0 by legacy software.
D4.2 The VMSA v8-64 address translation system

The following subsections describe the VMSA v8-64 address translation system, that maps VAs to PAs:

- About the VMSA v8-64 address translation system.
- The implemented Exception levels and the resulting translation stages and regimes on page D4-2095.
- Controlling address translation stages on page D4-2095.
- Memory translation granule size on page D4-2104.
- Translation tables and the translation process on page D4-2110.
- Overview of the VMSA v8-64 address translation stages on page D4-2113.
- The VMSA v8-64 translation table format on page D4-2125.
- The algorithm for finding the translation table descriptors on page D4-2132.
- The effects of disabling a stage of address translation on page D4-2136.
- The implemented Exception levels and the resulting translation stages and regimes on page D4-2095.
- Pseudocode description of VMSA v8-64 address translation on page D4-2138.
- Address translation instructions on page D4-2139.

Related to this:

- VMSA v8-64 translation table format descriptors on page D4-2143 describes the translation table entries.
- Memory region attributes on page D4-2174 describes the attributes that are held in the translation table entries, including how different attributes can interact.
- Translation Lookaside Buffers (TLBs) on page D4-2201 describes the caching of translation table lookups in TLBs, and the architected instructions for maintaining TLBs.
- AArch64 Address translation examples on page K7-6480 gives detailed descriptions of typical examples of translating a VA to a final PA, and obtaining the memory attributes of that PA.

D4.2.1 About the VMSA v8-64 address translation system

The Memory Management Unit (MMU) controls address translation, memory access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The general model of MMU operation is that the MMU takes information about a required memory access, including an input address (IA), and either:

- Returns an associated output address (OA), and the memory attributes for that address.
- Is unable to perform the translation for one of a number of reasons, and therefore causes an exception to be generated. This exception is called an MMU fault. System registers are used to report any MMU faults that occur.

The process of mapping an IA to an OA is an address translation, or more precisely a single stage of address translation.

When using a VMSA, a translation regime maps a VA to a PA using one or two stages of translation, and:

- The AArch64 translation regimes on page D4-2092 defines the translation regimes.
- VMSA address types and address spaces on page D4-2083 give more information about VAs and PAs.

The translation granule specifies the granularity of the mapping from IA to OA. That is, it defines both:

- The page size for a stage of address translation, where a page is the smallest block of memory for which an IA to OA mapping can be specified.
- The size of a complete translation table for that stage of address translation.

The MMU is controlled by System registers, that provide independent control of each address translation stage, including a control to disable the stage of address translation. The effects of disabling a stage of address translation on page D4-2136 defines how the MMU handles an access for which a required address translation stage is disabled.
This section describes the address translation system for an implementation that includes all of the Exception levels, and gives a complete description of translations that are controlled by an Exception level that is using AArch64. In addition:

- The ARMv8 VMSA when some Exception levels are using AArch32 on page D4-2082 gives information about the VMSA when some Exception levels are using AArch32.
- The implemented Exception levels and the resulting translation stages and regimes on page D4-2095 describes the effect on the address translation model when some Exception levels are not implemented.

Each enabled stage of address translation uses a set of address translations and associated memory properties held in memory mapped tables called translation tables. A single translation table lookup can resolve only a limited number of bits of the IA, and therefore a single address translation can require multiple lookups. These are described as different levels of lookup.

Translation table entries can be cached in a Translation Lookaside Buffer (TLB).

As well as defining the OA that corresponds to the IA, the translation table entries define the following properties:

- For accesses made from Secure state, whether the access is to the Secure or Non-secure address map.
- Memory access permissions.
- Memory region attributes.

For more information, see Memory attribute fields in the VMSA-64 translation table format descriptors on page D4-2148.

The following subsections give more information:

- The AArch64 translation regimes.
- About address translation and supported input address ranges on page D4-2094.
- The VMSA-64 translation table format on page D4-2094.

The AArch64 translation regimes

The architecture defines a number of translation regimes, where a translation regime comprises either:

- A single stage of address translation. This maps an input VA to an output PA.
- Two, sequential, stages of address translation, where:
  - Stage 1 maps an input VA to an output IPA.
  - Stage 2 maps an input IPA to an output PA.

Figure D4-1 shows these translation stages and translation regimes when EL3 is using AArch64.

Translation regimes, when EL3 is using AArch64

| Secure EL3 | VA        | Secure EL3 stage 1 | PA, Secure or Non-secure |
| Secure EL1&0 | VA        | Secure EL1&0 stage 1 | PA, Secure or Non-secure |
| Non-secure EL2 or Non-secure EL2&0† | VA | Non-secure EL2 or EL2&0, stage 1 | PA, Non-secure only |
| Non-secure EL1&0 | VA | Non-secure EL1&0 stage 1 | PA, Non-secure only |

† Typically controlled from this Exception level, but also accessible from higher Exception levels
‡ Non-secure EL2&0 when the implementation includes ARMv8.1-VHE and the value of HCR_EL2.E2H is 1, otherwise Non-secure EL2.

Figure D4-1 VMSA-64 AArch64 translation regimes, translation stages, and associated controls
This means that in VMSAv8-64 the set of translation regimes is:

**The Secure EL3 translation regime**

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

**The Non-secure EL2 translation regime**

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range. In an implementation that:

- Does not include ARMv8.1-VHE this regime is used for all memory accesses from EL2.
- Includes ARMv8.1-VHE, this regime is used for memory accesses from EL2 only when the value of HCR_EL2.E2H is 0.

**The Non-secure EL2&0 translation regime**

This has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs. It is supported only by implementations that include ARMv8.1-VHE, and is used:

- For memory accesses from EL2 when the value of HCR_EL2.E2H is 1.
- For memory accesses from EL0 when the value of HCR_EL2.{E2H, TGE} is {1, 1}.

**The Secure EL1&0 translation regime**

This has a single stage of translation, stage 1, that maps VAs to PAs and can support two VA ranges and the use of ASIDs.

**The Non-secure EL1&0 translation regime**

If cached in a TLB, a translation table lookup for this regime is associated with the VMID that identifies the current virtual machine. This regime has two stages of lookup:

- **Stage 1**
  Maps VAs to IPAs. This stage can support two VA ranges and the use of ASIDs.
- **Stage 2**
  Maps IPAs to PAs. This stage supports a single IPA range.

An MMU fault might be generated by a particular stage of translation. An MMU fault is described as either a stage 1 MMU fault or a stage 2 MMU fault.

---

**Note**

- In the ARM architecture, a software agent, such as an operating system, that uses or defines stage 1 memory translations, might be unaware of the second stage of translation, and of the distinction between IPA and PA.

- A more generalized description of the translation regimes is that a regime always comprises two sequential stages of translation, but in some regimes the stage 2 translation both:
  - Returns an OA that equals the IA. This is called a flat mapping of the IA to the OA.
  - Does not change the memory attributes returned by the stage 1 address translation.

---

**Constraints on accesses from EL0 when EL0 is using AArch32**

ARMv8 permits execution with EL0 using AArch32 when the next higher Exception level is using AArch64. This happens in the following situations:

- EL1 is using AArch64. Execution at EL0 using AArch32 uses the VMSAv8-64 EL1&0 translation regime.
- EL2 is using AArch64 and the Effective value of HCR_EL2.{E2H, TGE} is {0, 1} or {1, 0}. Execution at EL0 using AArch32 uses the VMSAv8-64 EL1&0 translation regime.
- In an implementation that includes ARMv8.1-VHE, EL2 is using AArch64 and the value of HCR_EL2.{E2H, TGE} is {1, 1}. Execution at EL0 using AArch32 uses the VMSAv8-64 EL2&0 translation regime.

In this case, accesses from EL0 using AArch32 are using:

- The stated VMSAv8-64 translation regime, EL1&0 or EL2&0.
• The AArch32 memory model.

In particular, this means the accesses from EL0 are limited to a 32-bit VA range.

**About address translation and supported input address ranges**

For a single stage of address translation, a *Translation table base register (TTBR_ELx)* indicates the start of the first translation table required for a mapping from input address (IA) to output address (OA). For a stage of address translation that supports two VA ranges each VA range is an independent mapping from IA to OA. This means that each implemented translation stage shown in *VMSAv8 AArch64 translation regimes, translation stages, and associated controls on page D4-2092* requires:

- Two associated sets of translation tables if it supports two IA ranges.
- One associated set of translation tables if it supports a single IA range.

**Note**

- Stage 2 translations never support two IA ranges. This means that, for the translation stages that support two IA ranges the IA is always a VA.

*Example use of the split VA range, and the TTBR0_ELx and TTBR1_ELx controls on page D4-2129* shows how two supported VA ranges might be used.

**Controlling address translation stages on page D4-2095** summarizes the System registers that control address translation by the MMU, and *Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D4-2128* gives more information about the address translation stages that support two VA ranges.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single IA to OA translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level of address lookup*. The final level of the lookup defines:

- The high bits of the required output address.
- The *attributes and access permissions* of the addressed memory.

Translation table entries can be cached in a *Translation Lookaside Buffer*, see *Translation Lookaside Buffers (TLBs) on page D4-2201*.

**The VMSAv8-64 translation table format**

Stages of address translation that are controlled by an Exception level that is using AArch64 use the VMSAv8-64 translation table format. This format uses 64-bit descriptor entries in the translation tables.

**Note**

This format is an extension of the VMSAv8-32 Long-descriptor translation table format originally defined by the ARMv7 Large Physical Address Extension, and extended slightly by ARMv8. VMSAv8-32 also supports a Short-descriptor translation table format. *Chapter G4 The AArch32 Virtual Memory System Architecture* describes both of these formats.

The VMSAv8-64 translation table format provides:

- Up to four levels of address lookup.
- A translation granule size of 4KB, 16KB, or 64KB.
- Input addresses of:
  - Up to 52 bits if ARMv8.2-LVA is implemented and the 64KB translation granule is used.
  - Otherwise, up to 48 bits.
- Output addresses of:
  - Up to 52 bits if ARMv8.2-LPA is implemented and the 64KB translation granule is used.
  - Otherwise, up to 48 bits.

For more information about input address and output address sizes see *Address size configuration on page D4-2097*. 
D4.2.2  The implemented Exception levels and the resulting translation stages and regimes

About the VMSAv8-64 address translation system on page D4-2091 describes an implementation that includes all Exception levels. Controlling address translation stages describes the control of address translation by Exception levels that are using AArch64. This subsection describes how the address translation scheme changes if an implementation does not include all of the Exception levels.

If an implementation does not include EL3, it has only a single Security state, with MMU controls equivalent to the Secure state MMU controls.

If an implementation does not include EL2 then:
- If it also does not include EL3, the MMU provides only a single EL1&0 stage 1 translation regime.
- If it includes EL3, the MMU provides an EL1&0 stage 1 translation regime in each Security state.

Figure D4-1 on page D4-2092 shows the set of translation regimes for an implementation that implements all of the Exception levels. Table D4-1 shows how the supported translation stages depend on the implemented Exception levels, and in some cases on the Execution state being used by the highest implemented Exception level.

Table D4-1 The relation between the implemented translation stages and Exception levels for AArch64

<table>
<thead>
<tr>

<td>• Only EL1 and EL0 implemented, with all operation in the Secure state.</td>
</tr>
</tbody>
</table>

a. The Non-secure EL2&0 translation regime is supported only if an implementation includes ARMv8.1-VHE. When supported, it is used when the value of HCR_EL2.E2H is 1.

D4.2.3  Controlling address translation stages

The implemented Exception levels and the resulting translation stages and regimes defines the translation regimes and stages. For each supported address translation stage:
- A System register bit enables the stage of address translation.
- A System register bit determines the endianness of the translation table lookups.
- A Translation Control Register (TCR_ELx) controls the stage of address translation.
- If a stage of address translation supports two VA ranges then that stage of translation provides:
  - A single TCR_ELx.
  - A TTBR_ELx for each VA range. TTBR0_ELx points to the translation tables for the address range that starts at 0x0000000000000000, and TTBR1_ELx points to the translation tables for the address range that ends at 0xFFFFFFFFFFFFFFFF.

Otherwise, a stage of translation provides a single TCR_ELx and a single TTBR_ELx that holds the address of the translation table that must be used for the first lookup for the stage of address translation.
For address translation stages controlled from AArch64:

- Table D4-2 shows the endianness bit (EE) and the enable bit (M or VM) for each stage of address translation. Each register entry in the table gives the endianness bit followed by the enable bit.

<table>
<thead>
<tr>
<th>Translation stage</th>
<th>Controlled from</th>
<th>Controlling register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure EL3 stage 1</td>
<td>EL3</td>
<td>SCTLR_EL3.{EE, M}</td>
</tr>
<tr>
<td>Secure EL1&amp;0 stage 1</td>
<td>Secure EL1</td>
<td>SCTLR_EL1.{EE, M}</td>
</tr>
<tr>
<td>Non-secure EL2 stage 1 or Non-secure EL2&amp;0 stage 1</td>
<td>EL2</td>
<td>SCTLR_EL2.{EE, M}</td>
</tr>
<tr>
<td>Non-secure EL1&amp;0 stage 2</td>
<td>EL2</td>
<td>SCTLR_EL2.EE, HCR_EL2.VM</td>
</tr>
<tr>
<td>Non-secure EL1&amp;0 stage 1</td>
<td>Non-secure EL1</td>
<td>SCTLR_EL1.{EE, M}</td>
</tr>
</tbody>
</table>

- The Non-secure EL2&0 translation regime is supported only if an implementation includes ARMv8.1-VHE. When supported, it is used when the value of HCR_EL2.E2H is 1.

---

**Note**

If the **PA** of the software that enables or disables a particular stage of address translation differs from its **VA**, speculative instruction fetching can cause complications. ARM strongly recommends that the **PA** and **VA** of any software that enables or disables a stage of address translation are identical if that stage of translation controls translations that apply to the software currently being executed.

- Table D4-3 shows the **TCR_ELx** and **TTBR_ELx**, or **TTBR_ELxs**, for each stage of address translation. In the table, each **Controlling registers** entry gives the **TCR_ELx** followed by the **TTBR_ELx** or **TTBR_ELxs**.

<table>
<thead>
<tr>

<td>TCR_EL1, TTBR0_EL1, TTBR1_EL1</td>
</tr>
</tbody>
</table>

- The Non-secure EL2&0 translation regime is supported only if an implementation includes ARMv8.1-VHE. When supported, it is used when the value of HCR_EL2.E2H is 1.

The following subsections give more information about controlling address translation:

- **System registers relevant to MMU operation** on page D4-2097.
- **Address size configuration** on page D4-2097.
- **Atomicity of register changes on changing virtual machine** on page D4-2103.
- **Use of out-of-context translation regimes** on page D4-2103.
System registers relevant to MMU operation

In AArch64 state, System registers have a suffix, that indicates the lowest Exception level from which they can be accessed. In some general descriptions of MMU control and address translation, this chapter uses a Common abbreviation for each of the System registers that affects MMU operation, as Table D4-4 shows. The common abbreviation is used when describing features that apply to multiple translation regimes or stages.

______ Note ______
The only translation regime that supports a stage 2 translation is the Non-secure EL1&0 translation regime.

Address size configuration

The following subsubsections specify the configuration of the PA size and of the input and output address sizes for each of the stages of address translation:

• Physical address size.
• Output address size on page D4-2098.
• Input address size on page D4-2099.
• Supported IPA size on page D4-2100.

Physical address size

The ID_AA64MMFR0_EL1.PARange field indicates the implemented PA size, as Table D4-5 shows.

<table>
<thead>
<tr>
<th>ID_AA64MMFR0_EL1.PARange</th>
<th>Total PA size</th>
<th>PA address size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>4 GB</td>

</tr>
<tr>
<td>0001</td>
<td>64 GB</td>
<td>36 bits, PA[35:0]</td>
</tr>
<tr>
<td>0010</td>
<td>1 TB</td>
<td>40 bits, PA[39:0]</td>
</tr>
<tr>
<td>0011</td>
<td>4 TB</td>
<td>42 bits, PA[41:0]</td>
</tr>
</tbody>
</table>

Table D4-5 Physical address size implementation options
All other PARange values are reserved.

**Output address size**

For each enabled stage of address translation, TCR_ELx.{I}PS must be programmed to maximum output address size for that stage of translation, using the encodings as shown in Table D4-6.

<table>
<thead>
<tr>

</tbody>
</table>

a. Only when an implementation includes ARMv8.2-LPA and is using the 64KB translation granule, see Extending addressing above 48 bits on page D4-2101.

---

**Note**

- The naming of this field is as follows:
  - IPS
    - In TCR_EL1.
    - In an implementation that includes ARMv8.1-VHE, in TCR_EL2 when the value of HCR_EL2.E2H is 1.
  - PS
    - Otherwise.

- The {I}PS fields are 3-bit fields, corresponding to the least-significant PARange bits shown in Table D4-5 on page D4-2097.

If {I}PS is programmed to a value larger than the implemented PA size, then the PE behaves as if programmed with the implemented PA size, but software must not rely on this behavior. That is, the output address size is never larger than the implemented PA size. Table D4-5 on page D4-2097 shows the implemented PA size.

The PE checks that the TTBR_ELx, translation table entries, and the output address for the stage of address translation have the address bits above the output address size set to zero. If this is not the case, an Address size fault is generated for the level and stage of translation that caused the fault. An Address size fault from the TTBR_ELx is always reported as a level 0 fault. When ARMv8.2-LPA is implemented and a translation granule of 4KB or 16KB is in use, all output addresses are treated as having bits[51:48] set to 0b0000.
If stage 1 translation is disabled and the input address is larger than the implemented PA size, then a stage 1 level 0 Address size fault is generated.

--- Note ---

These faults are reported as level 0 faults even if they occur in a translation stage that does not perform level 0 lookups.

---

When using two stages of translation:

- If stage 2 translation is disabled and the output address from the stage 1 translation is larger than the implemented PA size, then a stage 1 Address size fault is generated for the level of the stage 1 translation that generated the output address.

- If stage 2 translation is enabled and the output address from the stage 1 translation does not generate a stage 1 Address size fault, but is larger than the input address size specified for the stage 2 translation, then a stage 2 Translation fault is generated.

**Input address size**

For each enabled stage of address translation, the TCR_ELx.TxSZ fields specify the input address size:

For a stage of translation that can support two VA ranges

The TCR_ELx has two TxSZ fields, corresponding to the two VA ranges:
- TCR_ELx.T0SZ specifies the size for the lower VA range, translated using TTBR0_ELx.
- TCR_ELx.T1SZ specifies the size for the upper VA range, translated using TTBR1_ELx.

For a stage of translation that supports only a single input address (IA) range

The TCR_ELx has a single T0SZ field, and IAs are translated using TTBR0_ELx.

Attempting to translate an address that is larger than the configured input address size generates a Translation fault. This means:

- For a TCR_ELx with a single T0SZ field and a 48-bit address size, Figure D4-2 shows the input address map:

  ![Input address map](image)

  **Figure D4-2 AArch64 input address map when using a single TTBR and 48-bit input address size**

  - For a TCR_ELx with two TxSZ fields, the input address is always a VA, and Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D4-2128 describes the VA address map.

For the Non-secure EL1&0 translation regime, when both stages of translation are enabled, if the output address from the stage 1 translation does not generate a stage 1 address size fault, and is larger than the input address specified by VTCR_EL2.T0SZ, then the input address size check for the stage 2 translation generates a Translation fault.
Although software can configure the input address size to be smaller than 48 bits, all implemented AArch64 TTBR_ELxs must support input address sizes of up to 48 bits, and in an implementation that includes ARMv8.2-LVA, all TTBR_ELxs must support input address sizes of up to 52 bits.

*Overview of the VMSAv8-64 address translation stages on page D4-2113* gives more information about the relationship between the required input address size, the value of TxSZ, and the required initial lookup level, and how these are affected by the translation granule size. However:

**For all translation stages**

The maximum TxSZ value is 39. If TxSZ is programmed to a value larger than 39 then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field is programmed to 39 for all purposes other than reading back the value of the field.
- Any use of the TxSZ value generates a Level 0 Translation fault for the stage of translation at which TxSZ is used.

**For a stage 1 translation**

The effective minimum value of TxSZ is 16 if ARMv8.2-LVA is not supported or if the translation granule that is in use is 4KB or 16KB in size. When ARMv8.2-LVA is supported, for the 64KB translation granule size only, the effective minimum value of TxSZ is 12.

If TxSZ is programmed to a value smaller than the effective minimum value, and if ARMv8.2-LVA is not supported, then it IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field were programmed to 16 for all purposes other than reading back the value of the field.
- Any use of the TxSZ value generates a stage 1 level 0 Translation fault.

If TxSZ is programmed to a value smaller than the effective minimum value when ARMv8.2-LVA is supported, then any use of the TxSZ value generates a stage 1 level 0 Translation fault.

For more information, see *Extending addressing above 48 bits on page D4-2101*.

**For a stage 2 translation**

*Supported IPA size* defines the effective minimum value of T0SZ, that depends on the supported PA size, and also describes the possible effects of programming T0SZ to a value that is smaller than this effective minimum value.

**Supported IPA size**

For the Non-secure EL1&0 translation regime, the maximum IPA size is the maximum input address size for the second stage of translation, that must be specified by VTCR_EL2.T0SZ, see *Input address size on page D4-2099*. This value is constrained by the implemented PA size that is specified by ID_AA64MMFR0_EL1.PARange, see *Physical address size on page D4-2097*. This implemented PA size also constrains the maximum value of VTCR_EL2.SL0, that specifies the level of the initial lookup. SL0 also depends on the translation granule, as described in *Overview of the VMSAv8-64 address translation stages on page D4-2113*.

**Table D4-7 PA size implications for the VTCR_EL2.{T0SZ, SL0} fields**

<table>
<thead>

</tbody>
</table>
If VTCR_EL2.SL0 is programmed to a value larger than the maximum value shown in Table D4-7 on page D4-2100, or is programmed to a reserved value, then any memory access that uses the second stage of translation generates a stage 2 level 0 Translation fault.

If VTCR_EL2.T0SZ is programmed to a value smaller than the effective minimum value shown in Table D4-7 on page D4-2100, and if ARMv8.2-LPA is not implemented, then the implementation consistently does one of the following:

• Treats the VTCR_EL2.T0SZ field as being programmed to the effective minimum value for all purposes other than reading back the value of the field.

• Treats the VTCR_EL2.T0SZ field as being programmed to the effective minimum value for all purposes other than:
  — Reading back the value of the field.
  — Checking whether the value of VTCR_EL2.T0SZ is consistent with the value of VTCR_EL2.SL0.

• Generates a stage 2 level 0 Translation fault on any memory access that uses the second stage of translation.

If T0SZ is programmed to a value smaller than the effective minimum value when ARMv8.2-LPA is supported, then any use of the T0SZ value generates a stage 2 level 0 Translation fault.

For more information, see Extending addressing above 48 bits.

---

**Note**

Programming VTCR_EL2.T0SZ to a value smaller than the effective minimum value shown in Table D4-7 on page D4-2100 can never provide support for a larger address range than the range given by the effective minimum value, because the stage 1 output address will give an Address size fault if it is larger than either:

• The PA size, for a VMSA8-64 stage 1 translation.

• 40 bits, for a VMSA8-32 stage 1 translation.

---

**Extending addressing above 48 bits**

ARMv8.2 defines the following options for supporting 52-bit addressing:

**ARMv8.2-LVA**

Supports 52-bit VAs when using the 64KB translation granule. The maximum IPA and PA sizes remain 48-bit unless ARMv8.2-LPA is implemented.

**ARMv8.2-LPA**

Supports 52-bit IPAs and PAs when using the 64KB translation granule. The maximum VA size remains 48-bit unless ARMv8.2-LVA is implemented.

ARMv8.2-LPA and ARMv8.2-LVA can be implemented independently of each other.

When using the 64KB translation granule, ARMv8.2-LPA supports Block descriptors in level 1 translation tables. In this case, a block covers a 4TB address range.

a. Only supported in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule size.

---

Table D4-7 PA size implications for the VTCR_EL2.{T0SZ, SL0} fields (continued)
In all cases, 52-bit address ranges are supported only when using the 64KB translation granule. Maximum address sizes when using the other translation granules remain 48-bit.

See Address size configuration on page D4-2097 for how to configure use of 52-bit VAs when an implementation includes ARMv8.2-LVA.

When using the 64KB translation granule, the 52-bit input address size is supported as follows:

- In an implementation that includes ARMv8.2-LVA, for stage 1 translations the minimum value of TCR_ELx.TnSZ field is 12.
  If TCR_ELx.TnSZ is programmed to a value less than 12, any use of the TCR_ELx.TnSZ bit generates a stage 1 level 0 Translation fault.

- In an implementation that includes ARMv8.2-LVA, for a stage 2 translation the effective minimum value of VTCR_EL2.T0SZ is 12.
  If VTCR_EL2.T0SZ is programmed to a smaller value than the effective minimum size, then any use of a stage 2 translation generates a stage 2 level 0 Translation fault.

Table D4-28 on page D4-2135 shows the translation table descriptor addressing for each level of lookup when using the 64KB translation granule.

In an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule:

- Bits[15:12] of each valid translation table descriptor hold bits[51:48] of the output address, or of the address of the translation table to be used for the initial lookup at the next level of translation. If the implementation does not support 52-bit physical addresses, then it is IMPLEMENTATION DEFINED whether non-zero values for these bits generate an Address size fault. In this case, not generating an Address Size Fault is deprecated.

- For a stage 1 translation, bits[5:2] of TTBR0_ELx or TTBR1_ELx holds bits[51:48] of the address of the translation table to be used for the initial lookup of that translation regime. If the implementation does not support 52-bit physical addresses, then non-zero values for these bits generate an Address size fault.

- For a stage 2 translation, bits[5:2] of VTTBR_EL2 holds bits[51:48] of the address of the translation table to be used for the initial lookup of the stage 2 translation. If the implementation does not support 52-bit physical addresses, then non-zero values for these bits generate an Address size fault.

- The minimum alignment of a translation table containing fewer than eight entries is 64 bytes.

--- Note ---

This is because, when the OA space is more than 48 bits, TTBR_ELx[5:2] specifies bits[51:48] of the translation table base address, and a translation table of fewer than eight entries would require one or more bits of TTBR_ELx[5:2] to be RES0 if the table was aligned to its size.

For more information, see VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats on page D4-2143 and ARMv8 translation table level 3 descriptor formats on page D4-2147.

The ID_AA64MMFR2_EL1.VA field indicates the supported VA size. This field has the value 0x1 if the implementation includes ARMv8.2-LVA.

The ID_AA64MMFR0_EL1.PArange field indicates the supported PA and IPA size. This field has the value 0x6 if the implementation supports 52-bit PAs.

In addition to the System registers discussed in this subsection, the ARMv8.2-LPA and ARMv8.2-LVA features affect the following System registers that contain addresses:

- HPFAR_EL2.
- PAR_EL1.
- VBAR_EL1, VBAR_EL2, VBAR_EL3.
- DBGBVR<n>_EL1.
- DBGWVR<n>_EL1.
- MDRAR_EL1.
• LOREA_EL1.
• LORSA_EL1.

The larger VA, IPA, and PA addresses also affect the following system instructions for TLB maintenance:
• TLBI IPAS2E1.
• TLBI IPAS2E1IS.
• TLBI IPAS2LE1.
• TLBI IPAS2LE1IS.

**Atomicity of register changes on changing virtual machine**

From the viewpoint of software executing at Non-secure EL1 or EL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the Non-secure EL1&0 translation regime. This means that all of the following registers must change atomically:

- The registers associated with the stage 1 translations:
  - MAIR_EL1 and AMAIR_EL1.
  - TTBR0_EL1, TTBR1_EL1, TCR_EL1, and CONTEXTIDR_EL1.
  - SCTLR_EL1.

- The registers associated with the stage 2 translations:
  - VTTBR_EL2 and VTCR_EL2.
  - SCTLR_EL2.

**Note**

Only some bits of SCTLR_EL1 affect the stage 1 translation, and only some bits of SCTLR_EL2 affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure EL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are out of context when they are updated, and no synchronization precautions are required.

Similar considerations apply when ARMv8.1-VHE is implemented.

**Use of out-of-context translation regimes**

The architecture requires that:

- When executing at EL3, EL2, or Secure EL1, the PE must not use the registers associated with the Non-secure EL1&0 translation regime for speculative memory accesses.
- When executing at EL3 or Secure EL1, the PE must not use the registers associated with the EL2, or EL2&0 translation regime for speculative memory accesses.
- When executing at EL3, EL2, or Non-secure EL1, the PE must not use the registers associated with the Secure EL1&0 translation regime for speculative memory accesses.

When entering an Exception level, on completion of a DSB instruction, no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered will be observed by any observers, to the extent that those accesses are required to be observed as determined by the shareability and cacheability of those translation table entries.
D4.2.4 Memory translation granule size

The memory translation granule size defines both:
- The maximum size of a single translation table.
- The memory page size. That is, the granularity of a translation table lookup.

VMSAv8-64 supports translation granule sizes of 4KB, 16KB, and 64KB. Support for each granule size is optional, and is indicated as shown in Table D4-8:

<table>
<thead>
<tr>
<th>Granule size</th>
<th>Support indicated by:</th>
<th>Values</th>
<th>Support indicated by:</th>
</tr>
</thead>
<tbody>
<tr>
<td>4KB</td>
<td>ID_AA64MMFR0_EL1.TGRAN4</td>
<td>0b0000</td>
<td>4KB granule size supported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0b1111</td>
<td>4KB granule size not supported.</td>
</tr>
<tr>
<td>16KB</td>
<td>ID_AA64MMFR0_EL1.TGRAN16</td>
<td>0b0000</td>
<td>16KB granule size not supported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0b0001</td>
<td>16KB granule size supported.</td>
</tr>
<tr>
<td>64KB</td>
<td>ID_AA64MMFR0_EL1.TGRAN64</td>
<td>0b0000</td>
<td>64KB granule size supported.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0b1111</td>
<td>64KB granule size not supported.</td>
</tr>
</tbody>
</table>

In VMSAv8-64, each address translation stage is configured, independently, to use one of the supported granule sizes.

--- Note ---
- Using a larger granule size can reduce the maximum required number of levels of address lookup because:
  - The increased translation table size means the translation table holds more entries. This means a single lookup can resolve more bits of the input address.
  - The increased page size means more of the least-significant address bits are required to address a page. These address bits are flat mapped from the input address to the output address, and therefore do not require translation.
- ARM recommends that memory-mapped peripherals are separated by an integer multiple of the largest granule size supported by the operating system or hypervisor, to allow each peripheral to be managed independently.

---
Table D4-9 summarizes the effects of the different granule sizes.

<table>

</tr>
</tbody>
</table>

**How the granule size affects the address translation process**

As Table D4-9 shows, the translation granule determines the number of address bits:

- Required to address a memory page.
- That can be resolved in a single translation table lookup.

This means the translation granule determines how the input address (IA) is resolved to an output address (OA) by the translation process.

Because a single translation table lookup can resolve only a limited number of address bits, the IA to OA resolution requires multiple levels of lookup.

Considering the resolution of an IA range of 48 bits, with a translation granule size of $2^n$ bytes:

- The least-significant $n$ bits of the IA address the memory page. This means OA[($n$-1):0]=IA[($n$-1):0].
- The remaining (48-$n$) bits of the IA, IA[47:$n$], must be resolved by the address translation.
- A translation table descriptor is 8 bytes. Therefore:
  — A complete translation table holds $2^{(n-3)}$ descriptors.
  — A single level of translation can resolve a maximum of $(n-3)$ bits of address.

Consider the translation process, working back from the final level of lookup, that resolves the least significant of the address bits that require translation. Because the translation needs to resolve IA[47:$n$] and a level of lookup can resolve (n-3) bits of address:

- The final level of lookup resolves IA[(2n-4):$n$].
- The previous level of lookup resolves IA[(3n-7):(2n-3)].

However, the level of lookup that resolves the most significant bits of the IA might not require a full-sized translation table. Therefore, in general, for a 48-bit IA the address bits resolved in a level of lookup are:

$IA[Min(47, (m(n-3)+(n-2)+2n-4):(n+(n-3)-(n-3))]$, where:

$Min(a, \ b)$ is a function that returns the minimum of $a$ and $b$.

$m$ indicates the level of lookup. This is defined so that the level that resolves the least significant bit of the translated IA bits is level 3.

The following diagrams show this model, for each of the permitted granule sizes.

Figure D4-3 on page D4-2106 shows how a 48-bit IA is resolved when using the 4KB translation granule.
Figure D4-3 How a 48-bit IA is resolved when using the 4KB translation granule

Figure D4-4 shows how a 48-bit IA is resolved when using the 16KB translation granule.

Figure D4-4 How a 48-bit IA is resolved when using the 16KB translation granule
Figure D4-5 shows how a 48-bit IA is resolved when using the 64KB translation granule.

In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule:

- The IA range that can be addressed by the level 1 lookup is IA[51:42].
- The level 1 lookup can directly address a block of memory, returning OA[51:42].

Note

The increased IA range means the size of the indexed level 1 translation table is increased.

Later sections of this chapter give more information about the translation process, and explain the terminology used in these figures.

Effect of granule size on translation table addressing and indexing

Table D4-10 shows the effect of the translation granule size on the addressing and indexing of the TTBR_ELx, and on the input address range that must be resolved.

<table>
<thead>

</tbody>
</table>

- a. Smaller value than indicated in Table D4-10 on page D4-2107, as explained in this section.
- b. Level 0 lookup not possible with 64KB granule size.
- c. The second entry applies to an implementation that includes ARMv8.2-LVA and has selected an IA space larger than 47 bits, see Extending addressing above 48 bits on page D4-2101, The first entry applies otherwise.

Table D4-10 on page D4-2107 refers to accessing a complete translation table, of 4KB, 16KB, or 64KB. However, the ARMv8 translation system supports the following possible variations from the information in Table D4-10 on page D4-2107:

**Reduced IA width**

Depending on the configuration and implementation choices, the required input address width for the initial level of lookup might be smaller than the number of address bits that can be resolved at that level. This means that, for this initial level of lookup:

- The translation table size is reduced. For each 1 bit reduction in the input address size the size of the translation table is halved.

**Note**

- This has no effect on the translation table size for subsequent levels of lookup, for which the lookups always use full-sized translation tables.
- For a stage 2 translation, it might be possible to start the translation at a lower level, see Concatenated translation tables on page D4-2109.

- More low-order TTBR_ELx bits are needed to hold the translation table base address.

**Example D4-1** shows how this applies to translating a 35-bit input address range using the 4KB granule.

**Example D4-1 Effect of an IA width of 35 bits when using the 4KB granule size**

With a 4KB granule size, a single level of lookup can resolve up to 9 bits of IA. If an implementation has a 35-bit input address range, IA[34:0], Table D4-11 shows that lookup must start at level 1, and that the initial lookup must resolve IA[34:30], meaning it resolves 5 bits of address: This 4-bit reduction in the required resolution means:

- The translation table size is divided by \( 2^4 \), giving a size of 256B.

- The TTBR_ELx requires 4 more bits for the translation table base address, which becomes TTBR_ELx[47:8].

When using the 64KB translation granule to translate the maximum IA size of 48 bits, Table D4-11 shows that a level 1 lookup must resolve only IA[47:42]. This is 6 bits of address, compared to the 13 bits that can be resolved at a single level of lookup. This 7-bit reduction in the required resolution means:

- The translation table size is divided by \( 2^7 \), giving a size of 512B.
• The TTBR_ELx requires 7 more bits for the translation table base address, which becomes TTBR_ELx[47:9].

Concatenated translation tables

For stage 2 address translations, for the initial lookup, up to 16 translation tables can be concatenated. This means additional IA bits can be resolved at that lookup level. The block of concatenated translation tables must be aligned to the size of the block of translation tables.

This means that each additional IA bit resolved:
• Doubles the number of translation tables required. Resolving an additional \( n \) bits requires \( 2^n \) concatenated translation tables at the initial lookup level.
• Reduces by 1 bit the width of the translation table base address held in the TTBR_ELx.

This means that, for the initial lookup of a stage 2 translation table, the IA ranges shown in Table D4-11 on page D4-2108 can be extended by up to 4 bits. Example D4-2 shows how concatenation can be used to resolve a 40-bit IA when using the 4KB translation granule.

Example D4-2 Concatenating translation tables to resolve a 40-bit IA range, with the 4K granule

Table D4-11 on page D4-2108 shows that, when using the 4KB translation granule, a level 1 lookup can resolve a 39-bit IA, with the first lookup resolving IA[38:30]. For a stage 2 translation, to extend the IA width to 40 bits and resolve IA[39:30] with the first lookup:
• Two translation tables are concatenated, giving a total size of 8KB.
• The TTBR_ELx requires 1 fewer bit for the translation table base address, which becomes TTBR_ELx[47:13].

For more information, see Use of concatenated translation tables for the initial stage 2 lookup on page D4-2130.

In all cases, the translation table, or block of concatenated translation tables, must be aligned to the actual size of the table or block of concatenated tables.

The translation table base address held in the TTBR_ELx is defined in the OA map for that stage of address translation. The information given in this section assumes this stage of translation has the maximum OA size, meaning the translation table base address is:
• TTBR_ELx[47:12] if using the 4KB translation granule.
• TTBR_ELx[47:14] if using the 16KB translation granule.
• TTBR_ELx[47:16] if using the 64KB translation granule with an OA of 48 bits.
• In an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule, OA[51:16], where:
  — TTBR_ELx[5:2] holds OA[51:48].
  — TTBR_ELx[47:16] holds OA[47:16].

If the OA address is smaller than 48 bits then the upper bits of this field must be written as zero. For example, for a 40-bit OA range:
• If using the 4KB translation granule:
  — TTBR_ELx[47:40] must be set to zero.
  — TTBR_ELx[39:12] holds the translation table base address.
• If using the 16KB translation granule:
  — TTBR_ELx[47:40] must be set to zero.
  — TTBR_ELx[39:14] holds the translation table base address.
• If using the 64KB translation granule:
  — TTBR_ELx[47:40] must be set to zero.
  — TTBR_ELx[39:16] holds the translation table base address.
In all cases, if $TTBR\_ELx[47:40]$ is not zero, any attempt to access the translation table generates an Address size fault.

### D4.2.5 Translation tables and the translation process

The following subsections describe general properties of the translation tables and translation table walks, that are largely independent of the translation table format:

- Translation table walks.
- Ordering of memory accesses from translation table walks on page D4-2112.
- Security state of translation table lookups on page D4-2112.
- Control of translation table walks on page D4-2112.

See also Selection between $TTBR0\_ELx$ and $TTBR1\_ELx$ when two VA ranges are supported on page D4-2128.

#### Translation table walks

A translation table walk comprises one or more translation table lookups. The translation table walk is the set of lookups that are required to translate the VA to the PA. For the Non-secure EL1&0 translation regime, this set includes lookups for both the stage 1 translation and the stage 2 translation, but translation table walk can also be used to refer to either:

- The set of lookups required for the stage 1 translation, that translates the VA to the IPA. This is the stage 1 translation table walk.
- The set of lookups required for the stage 2 translation, that translates the IPA to the PA. This is the stage 2 translation table walk.

The information returned by a successful translation table walk is:

- The required PA. If the access is from Secure state this includes identifying whether the access is to the Secure PA space or the Non-secure PA space, see Security state of translation table lookups on page D4-2112.
- The memory attributes for the target memory region, as described in Memory types and attributes on page B2-114. For more information about how the translation table descriptors specify these attributes see Memory region attributes on page D4-2174.
- The access permissions for the target memory regions. For more information about how the translation table descriptors specify these permissions see Memory access control on page D4-2155.

The translation table walk starts with a read of the translation table for the initial lookup. The $TTBR\_ELx$ for the stage of translation holds the base address of this table. Each translation table lookup returns a descriptor, that indicates one of the following:

- The entry is the final entry of the walk. In this case, the entry contains the OA, and the permissions and attributes for the access.
- An additional level of lookup is required. In this case, the entry contains the translation table base address for that lookup. In addition:
  - The descriptor provides hierarchical attributes that are applied to the final translation, see Hierarchical control of Secure or Non-secure memory accesses on page D4-2154 and Hierarchical control of data access permissions on page D4-2159.
  - If the translation is in a Secure translation regime, the descriptor indicates whether that base address is in the Secure or Non-secure address space, unless a hierarchical control at a previous level of lookup has indicated that it must be in the Non-secure address space.
- The descriptor is invalid. In this case, the memory access generates a Translation fault.

Figure D4-6 on page D4-2111 gives a generalized view of a single stage of address translation where three levels of lookup are required.
A translation table lookup from VMSAv8-64 performs a single-copy atomic 64-bit access to the translation table entry. This means the translation table entry is treated as a 64-bit object for the purpose of endianness.

SCTLR_ELx.EE determines the endianness of the translation table lookups.

--- Note ---

Dynamically changing translation table endianness

Because any change to an SCTLR_ELx.EE, bit requires synchronization before it is visible to subsequent operations, ARM strongly recommends that any EE bit is changed only when either:

- Executing at an Exception level that does not use the translation tables affected by the EE bit being changed.
- Executing with address translation disabled for any stage of translation affected by the EE bit being changed.

Address translation stages are disabled by setting an SCTLR_ELx.M bit or the HCR_EL2.VM bit to 0. See the appropriate register description for more information.

---

The appropriate TTBR_ELx holds the output address of the base of the translation table used for the initial lookup, and:

- For all address translation stages other than Non-secure EL1&0 stage 1 translations, the output address held in the TTBR_ELx, and any translation table base address returned by a translation table descriptor, is the PA of the base of the translation table.
- For Non-secure EL1&0 stage 1 translations, the output address held in the TTBR_ELx, and any translation table base address returned by a translation table descriptor, is the IPA of the base of the translation table. This means that if stage 2 address translation is enabled, each of these OAs is subject to second stage translation.

--- Note ---

TLB caching can be used to minimize the number of translation table lookups that must be performed. For the Non-secure EL1&0 translation regime, because each stage 1 OA generated during a translation table walk is subject to a stage 2 translation, if the caching of translation table entries is ineffective, a VA to PA address translation with two stages of translation can give rise to multiple translation table lookups. The number of lookups required is given by the following equation:

\[(S1+1)*(S2+1) - 1\]

Where, for this translation regime, S1 is the number of levels of lookup required for a stage 1 translation, and S2 is the number of levels of lookup required for a stage 2 translation.
The TTBR_ELx also determines the memory cacheability and shareability attributes that apply, for the corresponding stage of translation, to all translation table lookups generated by that stage of translation.

The Normal memory type is the memory type defined for a translation table lookup for a stage of translation.

Note

• In a two stage translation regime, a translation table lookup from stage 1, that has the Normal memory type defined at stage 1 by this rule, can still be given the Device memory type as part of the stage 2 translation of that address. ARM strongly recommends against such a remapping of the memory type, and the architecture includes a trap of this behavior to EL2. For more information, see Stage 2 fault on a stage 1 translation table walk on page D4-2197.

• The rules about mismatched attributes given in Mismatched memory attributes on page B2-125 apply to the relationship between translation table walks and explicit memory accesses to the translation tables in the same way that they apply to the relationship between different explicit memory accesses to the same location. For this reason, ARM strongly recommends that the attributes that the TCR_ELx applies to the translation tables are the same as the attributes that are applied for explicit accesses to the memory that holds the translation tables.

For more information see Overview of the VMSAv8-64 address translation stages on page D4-2113.

See also Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D4-2128.

Ordering of memory accesses from translation table walks

A translation table walk is considered to be a separate observer, and:

• A write to the translation tables can be observed by that separate observer at any time after the execution of the instruction that performed that write, but is only guaranteed to be observable after the execution of a DSB instruction by the PE that executed the instruction that performed that write to the translation tables.

• Any writes to the translation tables are not seen by any explicit memory access generated by a load or store that occurs in program order before the instruction that performs the write to the translation tables.

Security state of translation table lookups

For a Non-secure translation regime, all translation table lookups are performed to Non-secure output addresses.

For a Secure translation regimes, the initial translation table lookup is performed to a Secure output address.

If the translation table descriptor returned as a result of that initial lookup points to a second translation table, then the NSTable bit in that descriptor determines whether that translation table lookup is made to Secure or to Non-secure output addresses.

This applies for all subsequent translation table lookups as part of that translation table walk, with the additional rule that any translation table descriptor that is returned from Non-secure memory is treated as if the NSTable bit in that descriptor indicates that the subsequent translation table lookup is to Non-secure memory.

Control of translation table walks

When stage 1 translations of a translation can support two VA ranges the TCR_ELx.{EPD0, EPD1} bits determine whether, for that regime, the two sets of translation tables for stage 1 are valid. EPD0 indicates whether the tables that TTBR0_ELx points to is valid, and EPD1 indicates whether the tables that TTBR1_ELx points to is valid. The effect of these bits is:

\[ \text{EPD}_n = 0 \]  
The translation tables are valid, and can be used for a translation table lookup.

\[ \text{EPD}_n = 1 \]  
If a TLB miss occurs based on TTBR_ELx, a Translation fault is returned, and no translation table walk is performed. The fault is reported as a level 0 fault.
Overview of the VMSAv8-64 address translation stages

As shown in Memory translation granule size on page D4-2104, the granule size determines significant aspects of the address translation process. Effect of granule size on translation table addressing and indexing on page D4-2107 shows, for each granule size:

- How the required input address range determines the required initial lookup levels.
- For stage 2 translations, the possible effect described in Concatenated translation tables on page D4-2109.
- The TTBR_ELx addressing and indexing for the initial lookup.

The following subsections summarize the multiple levels of lookup that can be required for a single stage of address translation that might require the maximum number of lookups:

- Overview of VMSAv8-64 address translation using the 4KB translation granule.
- Overview of VMSAv8-64 address translation using the 16KB translation granule on page D4-2117.
- Overview of VMSAv8-64 address translation using the 64KB translation granule on page D4-2121.

Overview of VMSAv8-64 address translation using the 4KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 4KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR_ELx.TnSZ field. When using the 4KB translation granule, Table D4-12 shows this requirement.

Table D4-12 TCR_ELx.TnSZ values and IA ranges, 4K granule with no concatenation of tables

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>TnSZ values for and input address rangesa for starting at this level</th>
</tr>
</thead>
<tbody>
<tr>

<td>TnSZmin</td>
</tr>
<tr>
<td>0</td>
<td>16</td>
</tr>
<tr>
<td>1</td>
<td>25</td>
</tr>
<tr>
<td>2</td>
<td>34</td>
</tr>
</tbody>
</table>

a. The IAs show the address bits to be resolved when addressing a page of memory, see the Note that follows.

These configuration options are also permitted for stage 2 translations.

Note

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA; When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.
Figure D4-7 shows the stage 1 address translation, for an address translation using the 4KB granule with an input address size greater than 39 bits.

Overview of stage 2 translations, 4KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see Use of concatenated translation tables for the initial stage 2 lookup on page D4-2130.

When using the 4KB translation granule, Table D4-13 shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-13 VTCR_EL2.T0SZ values and IA ranges, 4K granule with possible concatenation of translation tables

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>T0SZ</th>
<th>IA</th>
<th>T0SZ</th>
<th>IA</th>
<th>T0SZ</th>
<th>IA</th>
<th>T0SZ</th>
<th>IA</th>
<th>T0SZ</th>
<th>IA</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16-24</td>
<td>IA[47:12]-IA[39:12]</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

a. Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in Table D4-12 on page D4-2113.

b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the Note that follows.
Note

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 4KB translation granule, tables cannot be concatenated at level 0.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

In addition, VTCR_EL2.SL0 indicates the required initial lookup level, as Table D4-14 shows.

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>VTCR_EL2.SL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0b10</td>
</tr>
<tr>
<td>1</td>
<td>0b01</td>
</tr>
<tr>
<td>2</td>
<td>0b00</td>
</tr>
</tbody>
</table>

The VTCR_EL2.SL0 value 0b11 is reserved.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. Table D4-13 on page D4-2114 shows the permitted T0SZ values for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.
Figure D4-8 shows the stage 2 address translation, for an input address size of between 40 and 43 bits. For an input address size in this range, the lookup can start at either level 0 or level 1.

VTCR_EL2.SL0 defines the start level.

Starting at level 0

Starting at level 1

Up to 16 concatenated tables at the initial level

- d Indexed by IA[20:12]
Overview of VMSAv8-64 address translation using the 16KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 16KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR_ELx.TnSZ field. When using the 16KB translation granule, Table D4-15 shows this requirement.

Table D4-15 TCR_ELx.TnSZ values and IA ranges, 16K granule with no concatenation of tables

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>TnSZ values for and input address rangesa for starting at this level</th>
<th>IA&lt;sub&gt;max&lt;/sub&gt;</th>
<th>IA&lt;sub&gt;min&lt;/sub&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>16 IA&lt;sub&gt;[47:14]&lt;/sub&gt;</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>1</td>
<td>17 IA&lt;sub&gt;[46:14]&lt;/sub&gt;</td>
<td>27 IA&lt;sub&gt;[36:14]&lt;/sub&gt;</td>
<td>-</td>
</tr>
<tr>
<td>2</td>
<td>28 IA&lt;sub&gt;[35:14]&lt;/sub&gt;</td>
<td>38 IA&lt;sub&gt;[25:14]&lt;/sub&gt;</td>
<td>-</td>
</tr>
<tr>
<td>3</td>
<td>39 IA&lt;sub&gt;[24:14]&lt;/sub&gt;</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

a. The IAs show the address bits to be resolved when addressing a page of memory, see the Note that follows.

The configuration options for an initial lookup at level 1, level 2, or level 3 are also permitted for stage 2 translations, but stage 2 translation does not permit an initial lookup at level 0.

Note

- When using the 16KB translation granule, a maximum of 1 bit of IA is resolved by a level 0 lookup.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

Figure D4-9 shows the stage 1 address translation, for an address translation using the 16KB granule with an input address size of 48 bits.
Overview of stage 2 translations, 16KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see Use of concatenated translation tables for the initial stage 2 lookup on page D4-2130.

When using the 16KB granule, for a stage 2 translation with an input address sized of 48 bits, the initial lookup must be at level 1, with two concatenated translation tables at this level.

When using the 16KB translation granule, Table D4-16 shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-16 VTCR_EL2.T0SZ values and IA ranges, 16K granule with possible concatenation of translation tables

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>T0SZ IA</td>
<td>16</td>
<td>IA[47:14] - - - - - -</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note

- When using the 16KB translation granule for a stage 2 translation, the initial lookup cannot be at level 0. When a 48-bit input address is required, translation must start with a level 1 lookup using two concatenated translation tables.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

In addition, VTCR_EL2.SL0 indicates the required initial lookup level, as Table D4-17 shows.

Table D4-17 VTCR_EL2.SL0 values, 16KB granule

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>VTCR_EL2.SL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0b10</td>
</tr>
<tr>
<td>2</td>
<td>0b01</td>
</tr>
<tr>
<td>3</td>
<td>0b00</td>
</tr>
</tbody>
</table>

The VTCR_EL2.SL0 value 0b11 is reserved.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. Table D4-16 shows the permitted values of T0SZ for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.
When stage 2 translation supports a 48-bit input address range, translation must start with a level 1 lookup using two concatenated translation tables. Figure D4-10 shows the translation for this case.

**Figure D4-10 VMSAv8-64 stage 2 address translation, 16KB granule, 48 bit input address**
However, for an input address size of between 37 and 40 bits, Table D4-16 on page D4-2118 shows that translation can start with either a level 1 lookup or a level 2 lookup, and Figure D4-11 shows these options.

VTCR_EL2.SL0 defines the start level.

Starting at level 1

Starting at level 2

a. The IAs show the address bits to be resolved when addressing a page of memory, see the Note that follows.
b. Supported only if ARMv8.2-LVA is implemented and the 64KB translation granule is used, see Extending addressing above 48 bits on page D4-2101.

These configuration options are also permitted for stage 2 translations.

Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.
- When ARMv8.2-LPA is implemented, a level 1 block attribute is supported when using the 64KB granule.

Figure D4-12 on page D4-2122 shows the stage 1 address translation, for an address translation using the 64KB granule with an input address size greater than 42 bits.
### Overview of stage 2 translations, 64KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see Use of concatenated translation tables for the initial stage 2 lookup on page D4-2130.

When using the 64KB translation granule, Table D4-19 shows all possibilities for the initial lookup for a stage 2 translation.

#### Table D4-19 VTCR_EL2.T0SZ values and IA ranges, 64K granule with possible concatenation of translation tables

<table>
<thead>
<tr>
<th>Tables</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initial lookup level</td>
<td>T0SZ</td>
<td>IA</td>
<td>T0SZ</td>
<td>IA</td>
<td>T0SZ</td>
</tr>
<tr>
<td>1&lt;sup&gt;c&lt;/sup&gt;</td>
<td>12-21</td>
<td>IA[51:16]-IA[48:16]</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>1</td>
<td>16-21</td>
<td>IA[47:16]-IA[42:16]</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

- **a.** Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in Table D4-18 on page D4-2121.
- **b.** The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the Note that follows.
- **c.** Only supported if the PA size is 52 bits, see Extending addressing above 48 bits on page D4-2101.
Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 64KB translation granule, tables cannot be concatenated at level 1.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.

VTCR_EL2.SL0 indicates the required initial lookup level, as Table D4-20 shows.

<table>
<thead>
<tr>
<th>Initial lookup level</th>
<th>VTCR_EL2.SL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0b10</td>
</tr>
<tr>
<td>2</td>
<td>0b01</td>
</tr>
<tr>
<td>3</td>
<td>0b00</td>
</tr>
</tbody>
</table>

The VTCR_EL2.SL0 value 0b11 is reserved.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.\{T0SZ, SL0\} values. Table D4-19 on page D4-2122 shows the permitted values of T0SZ for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.
Figure D4-13 shows the stage 2 address translation, for an input address size of between 43 and 46 bits. This means the lookup can start at either level 1 or level 2.

VTCR_EL2.SL0 defines the start level.

Starting at level 1

Starting at level 2

Up to 16 concatenated tables at the initial level

b2 Indexed by IA[n:29], where IA width is (n+1) bits
c Indexed by IA[28:16]
D4.2.7 The VMSAv8-64 translation table format

This section provides the full description of the VMSAv8-64 translation table format, its use for address translations that are controlled by an Exception level using AArch64. For these translation regimes:

For a stage 1 translation that can support two VA ranges

- For the lower VA range, that uses TTBR0_ELx:
  - The TCR_ELx.{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
  - The TCR_ELx.TG0 field defines the Translation granule size.
- For the upper VA range, that uses TTBR1_ELx:
  - The TCR_ELx.{SH1, ORGN1, IRGN1} fields define memory region attributes for the translation table walks.
  - The TCR_ELx.TG1 field defines the Translation granule size.
- Each of TTBR0_ELx and TTBR1_ELx contains an ASID field, and the TCR_ELx.A1 field selects which of these specifies the ASID to use.

For a stage 1 translation that supports only one VA range

The translation table walks use TTBR0_ELx, and:

- The TCR_ELx.{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The TCR_ELx.TG0 field defines the Translation granule size.

For a stage 2 translation

The translation table walks use VTTBR_EL2, and:

- The VTCR_EL2.{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The VTCR_EL2.TG0 field defines the Translation granule size.

For the VMSAv8-64 translation table format, Overview of the VMSAv8-64 address translation stages on page D4-2113 summarizes the lookup levels, and Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats on page D4-2145 describes the translation table entries.

The following subsections describe the use of this translation table format:

- Translation granule size and associated block and page sizes on page D4-2126.
- Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported on page D4-2128.
- Use of concatenated translation tables for the initial stage 2 lookup on page D4-2130.
- Possible errors in programming the translation table registers on page D4-2131.
Translation granule size and associated block and page sizes

Table D4-21 shows the supported granule sizes, block sizes and page sizes, for the different granule sizes. For completeness, this table includes information for AArch32 state. In the table, the OA bit ranges are the OA bits that the translation table descriptor specifies to address the block or page of memory, in an implementation that supports a 48-bit OA range.

a. Only available when ARMv8.2-LPA is implemented, see Extending addressing above 48 bits on page D4-2101.

Bit[1] of a translation table descriptor identifies whether the descriptor is a block descriptor, and:

- The 4KB granule size supports block descriptors only in level 1 and level 2 translation tables.
- The 16KB granule size supports block descriptors only in level 2 translation tables.
- The 64KB granule size supports block descriptors in level 2 translation tables, and in level 1 translation tables when ARMv8.2-LPA is implemented and the implementation supports 52 bits of physical address. If the implementation does not support 52 bits of physical address, then encoding a block descriptor in a level 1 translation table generates a level 1 Translation fault.

If bit[1] of a descriptor is 0 in a translation table that does not support block descriptors then a translation table walk that accesses that descriptor generates a Translation fault.

For translations managed from AArch64 state, the following tables expand the information for each granule size, showing for an access to a single translation table at each lookup level:

- The maximum IA size, and the address bits that are resolved for that maximum size.
- The maximum OA range resolved by the translation table descriptors at this level, and the corresponding memory region size.
- The maximum size of the translation table. This is the size required for the maximum IA size.

Table D4-22 on page D4-2127 shows this information for the 4KB translation granule size, Table D4-23 on page D4-2127 shows this information for the 16KB translation granule size, and Table D4-24 on page D4-2127 shows this information for the 64KB translation granule size.

</tbody>
</table>

*a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.*

*b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.*
For the initial lookup level:

- If the IA range specified by the TCR_ELx.TxSZ field is smaller than the maximum size shown in these tables then this reduces the number of addresses in the table and therefore reduces the table size. The smaller translation table is aligned to its table size.

- For stage 2 translations, multiple translation tables can be concatenated to extend the maximum IA size beyond that shown in these tables. For more information see the stage 2 translation overviews in Overview of the VMSAv8-64 address translation stages on page D4-2113 and Use of concatenated translation tables for the initial stage 2 lookup on page D4-2130.

If a supplied input address is larger than the configured input address size, a Translation fault is generated.

Note

Larger translation granule sizes typically require fewer levels of translation tables to translate a particular size of VA.

For the TCR_ELx programming requirements for the initial lookup, see Overview of the VMSAv8-64 address translation stages on page D4-2113.

Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported

Every translation table walk starts by accessing the translation table addressed by the TTBR_ELx for the stage 1 translation for the required translation regime.

For a stage 1 translation that can support two VA ranges, Figure D4-14 shows this VA range split when using 48-bit VAs, and:

- TTBR0_ELx points to the initial translation table for the lower VA range, that starts at address 0x0000000000000000,
- TTBR1_ELx points to the initial translation table for the upper VA range, that runs up to address 0xffffffffffffff.

As Figure D4-14 shows, for 48-bit VAs:

- The address range translated using TTBR0_ELx is 0x0000000000000000 to 0xffffffffffffff.
- The address range translated using TTBR1_ELx is 0xffffffffffffff to 0xffffffffffffff.

In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, for 52-bit VAs:

- The address range translated using TTBR0_ELx is 0x0000000000000000 to 0xffffffffffffff.
- The address range translated using TTBR1_ELx is 0xffffffffffffff to 0xffffffffffffff.
Which TTBR_ELx is used depends only on the VA presented for translation. The most significant bits of the VA must all be the same value and:

- If the most significant bits of the VA are zero, then TTBR0_ELx is used.
- If the most significant bits of the VA are one, then TTBR1_ELx is used.

However, it is configurable whether VA[63:56] are considered when determining which TTBR_ELx is used, that is:

- In an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, whether the determination depends on VA[63:52] or on VA[55:52].
- Otherwise, whether the determination depends on VA[63:48] or on VA[55:48].

For more information about whether VA[63:56] are considered for this determination see Address tagging in AArch64 state on page D4-2084.

Note

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the TCR_ELx.TnSZ values and the region for which an access generates a Translation fault is wider than shown in Figure D4-14 on page D4-2128. That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. Possible errors in programming the translation table registers on page D4-2131 describes this possibility.

Example D4-3 shows a typical application of this VA split.

Example D4-3 Example use of the split VA range, and the TTBR0_ELx and TTBR1_ELx controls

An example of using the split VA range is:

**TTBR0_ELx** Used for process-specific addresses.

- Each process maintains a separate level 1 translation table. On a context switch:
  - TTBR0_ELx is updated to point to the level 1 translation table for the new context
  - TCR_ELx is updated if this change changes the size of the translation table
  - CONTEXTIDR_ELx is updated.

**TTBR1_ELx** Used for operating system and I/O addresses, that do not change on a context switch.

For each VA subrange, the input address size is 2(64-TnSZ), where TnSZ is one of TCR_ELx.{T0SZ, T1SZ},

This means the two VA subranges are:

**Lower VA subrange** 0x0000_0000_0000_0000 to (2(64-T0SZ) - 1).

**Upper VA subrange** (264 - 2(64-T1SZ)) to 0xFFFF_FFFF_FFFF_FFFF.

For the situation where the minimum TnSZ value is 16, corresponding to a maximum input address range of 48 bits, Example D4-4 shows the two VA subranges when T0SZ and T1SZ are both set to this minimum value.

Example D4-4 Maximum VA ranges when a stage of translation supports two ranges

The maximum VA subranges correspond to T0SZ and T1SZ each having a minimum value of 16. In this case the subranges are:

**Lower VA subrange** 0x0000_0000_0000_0000 to 0x0000_FFFF_FFFF_FFFF.

**Upper VA subrange** 0xFFFF_0000_0000_0000 to 0xFFFF_FFFF_FFFF_FFFF.

Figure D4-14 on page D4-2128 indicates the effect of varying the TnSZ values.
As described in *Overview of the VMSAv8-64 address translation stages* on page D4-2113, the TnSZ values also determine the initial lookup level for the translation.

**Use of concatenated translation tables for the initial stage 2 lookup**

*Overview of the VMSAv8-64 address translation stages* on page D4-2113 introduced the ability to concatenate translation tables for the initial stage 2 translation lookup. This section gives more information about that concatenation.

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- The stage 2 translation starts at that next translation level.

When using the 16KB translation granule, if a 48-bit input address size is required for the stage 2 translations, lookup must start with two concatenated translation tables at level 1.

The use of concatenated translation tables requires the software that is defining the translation to:

- Define the concatenated translation tables with the required overall alignment.
- Program VTTBR_EL2 to hold the address of the first of the concatenated translation tables.
- Program VTCR_EL2 to indicate the required input address range and initial lookup level.

**Note**

The use of concatenated translation tables avoids the overhead of an additional level of translation.

Concatenating additional translation tables at the initial level of lookup resolves additional address bits at that level. To resolve \( n \) additional address bits requires \( 2^n \) concatenated translation tables. Example D4-5 shows how, for level 1 lookups using the 4KB translation granule, translation tables can be concatenated to resolve three additional address bits.

**Example D4-5 Adding three bits of address resolution at level 1 lookup, using the 4KB granule**

When using the 4KB translation granule, a level 1 lookup with a single translation table resolves address bits[38:30]. To add three more address bits requires \( 2^3 \) translation tables, that is, eight translation tables. This means:

- The total size of the concatenated translation tables is \( 8 \times 4\,\text{KB} = 32\,\text{KB} \).
- This block of concatenated translation tables must be aligned to 32KB.
- The address range resolved at this lookup level is A[41:30], of which:
  - Bits A[41:39] select the 4KB translation table.
  - Bits A[38:30] index a descriptor within that translation table.
As an example of the concatenation of translation tables at the initial lookup level, when using the 4KB translation granule, Table D4-25 shows the possible uses of concatenated translation tables to permit lookup to start at level 1 rather than at level 0. For completeness, the table starts with the case where the required IPA range means lookup starts at level 1 with a single translation table at that level.

### Table D4-25 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule

</tbody>
</table>

<sup>a</sup> Required alignment of the set of concatenated level 2 tables.

**Note**

Because concatenation is permitted only for a stage 2 translation, the input addresses in the table are IPAs.

**Overview of the VMSAv8-64 address translation stages** on page D4-2113 identifies all of the possible uses of concatenation. In all cases, the block of concatenated translation tables must be aligned to the block size.

### Possible errors in programming the translation table registers

This subsection describes possible errors in programming the translation table registers.

**Misprogramming the VTCR_EL2.{T0SZ, SL0} fields**

For a stage 2 translation, the programming of the VTCR_EL2.{T0SZ, SL0} fields must be consistent. If these fields are not consistent, or if SL0 is programmed to a reserved value, any translation table walk that uses stage 2 translation generates a stage 2 level 0 Translation fault. For more information see **Overview of the VMSAv8-64 address translation stages** on page D4-2113.

**Misprogramming of the Contiguous bit**

For more information about the Contiguous bit, and the range of translation table entries that must have the bit set to 1 to mark the entries as contiguous, see **The Contiguous bit** on page D4-2178.

If one or more of the following errors is made in programming the translation tables, the TLB might contain overlapping entries:

- One or more of the contiguous translation table entries does not have the Contiguous bit set to 1.
- One or more of the contiguous translation table entries holds an output address that is not consistent with all of the entries pointing to the same aligned contiguous address range.
- The attributes and permissions of the contiguous entries are not all the same.

Such misprogramming of the translation tables means the output address, memory permissions, or attributes for a lookup might be corrupted, and might be equal to values that are not consistent with any of the programmed translation table values.

In some implementations, such misprogramming might also give rise to a TLB Conflict abort.
The architecture guarantees that misprogramming of the Contiguous bit cannot provide a mechanism for any of the following to occur:

- Software executing at EL1 or EL0 accessing regions of physical memory that are not accessible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.
- Software executing at EL1 or EL0 accessing regions of physical memory with attributes or permissions that are not possible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.
- Software executing in Non-secure state accessing Secure physical memory.

**Note**

Hardware implementations must ensure that use of the Contiguous bit cannot provide a mechanism for avoiding output address range checking. This might occur if a Contiguous bit block size of 0.5GB or 1GB is used in a system with the output address size configured to 4GB. The architecture permits the implemented mechanism for preventing any avoidance of output address range checking to suppress the use of the Contiguous bit for such entries in such a system.

Where the Contiguous bit is used to mark a set of blocks as contiguous, if the address range translated by a set of blocks marked as contiguous is larger than the size of the input address supported at a stage of translation used to translate that address at that stage of translation, as defined by the TCR_ELx.TxSZ field, then this is a programming error. An implementation is permitted, but not required, to:

- Treat such a block within a contiguous set of blocks as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation, as defined by the TCR_ELx.TxSZ field.
- Treat such a block within a contiguous set of blocks as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, as defined by the TCR_ELx.TxSZ field, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

When ARMv8.2-LVA is implemented, level 1 block descriptors for the 64KB granule do not support the Contiguous bit, and that field is RES0.

### D4.2.8 The algorithm for finding the translation table descriptors

This subsection gives the algorithms for finding the translation table descriptor that corresponds to a given IA, for each required level of lookup. The algorithms encode the descriptions of address translation given earlier in this section. The algorithm details depend on the translation granule size for the stage of address translation, see:

- *Finding the translation table descriptor when using the 4KB translation granule* on page D4-2133.
- *Finding the translation table descriptor when using the 16KB translation granule* on page D4-2134.
- *Finding the translation table descriptor when using the 64KB translation granule* on page D4-2135.

Each subsection uses the following terms:

- **BaseAddr** The base address for the level of lookup, as defined by:
  - For the initial lookup level, the value of the appropriate TTBR_ELx.BADDR field.
  - Otherwise, the translation table address returned by the previous level of lookup.
- **PAMax** The supported PA width, in bits.
- **IA** The supplied IA for this stage of translation.
The translation table size for this stage of translation:

- **For EL1&0 stage 1**: `TCR_EL1.T0SZ` or `TCR_EL1.T1SZ`, as appropriate.
- **For EL1&0 stage 2**: `VTCR_EL2.T0SZ`.
- **For EL2 stage 1**: `TCR_EL2.T0SZ`.
- **For EL2&0 stage 1**: `TCR_EL2.T0SZ` or `TCR_EL2.T1SZ`, as appropriate.
- **For EL3 stage 1**: `TCR_EL3.T0SZ`.

**SL0**

`VTCR_EL2.SL0`. Applies to the Non-secure EL1&0 stage 2 translation only.

These subsections show only architecturally-valid programming of the `TCR_ELx`. See also *Possible errors in programming the translation table registers* on page D4-2131.

### Finding the translation table descriptor when using the 4KB translation granule

Table D4-26 shows the translation table descriptor address, for each level of lookup, when using the 4KB translation granule. See the start of *The algorithm for finding the translation table descriptors* on page D4-2132 for more information about terms used in the table.

#### Table D4-26 Translation table entry addresses when using the 4KB translation granule

Table D4-8 on page D4-2104 shows how software can determine whether an implementation supports the 64KB granule size.
D4.2.9 The effects of disabling a stage of address translation

The following sections describe the effect on MMU behavior of disabling each stage of translation:

- **Behavior when stage 1 address translation is disabled**
- **Behavior when stage 2 address translation is disabled** on page D4-2137.
- **Behavior of instruction fetches when all associated stages of translation are disabled** on page D4-2137.

### Behavior when stage 1 address translation is disabled

When a stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of translation are treated as follows:

**Non-secure EL1 and EL0 accesses if the HCR_EL2.DC bit is set to 1**

For the Non-secure EL1&0 translation regime, when the value of HCR_EL2.DC is 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

---

**Note**

This applies for both instruction and data accesses.

---

**All other accesses**

For all other accesses, when stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

- **Data access**
  The stage 1 translation assigns the Device-nGnRnE memory type.

- **Instruction access**
  The stage 1 translation assigns the Normal memory attribute, with the cacheability and shareability attributes determined by the value of the SCTLR_ELx.I bit for the translation regime, as follows:

  **When the value of I is 0**
  The stage 1 translation assigns the Non-cacheable and Outer Shareable attributes.

  **When the value of I is 1**
  The stage 1 translation assigns the Cacheable, Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Outer Shareable attribute.

For this stage of translation, no memory access permission checks are performed. Therefore no MMU faults can be generated for this stage of address translation.

---

**Note**

Alignment checking is performed, and therefore Alignment faults can occur.

---

For every access, the input address of the stage 1 translation is flat-mapped to the output address.

For a Non-secure EL1 or EL0 access, if EL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

When the value of HCR_EL2.DC is 1, in Non-secure state:

- The SCTLR_EL1.M bit behaves as if it is 0, for all purposes other than reading the value of the bit. This means Non-secure EL1&0 stage 1 address translation is disabled.

- The HCR_EL2.VM bit behaves as if it is 1, for all purposes other than reading the value of the bit. This means that Non-secure EL1&0 stage 2 address translation is enabled.

See also **Behavior of instruction fetches when all associated stages of translation are disabled** on page D4-2137.
Effect of disabling address translation on maintenance and address translation instruction instructions

Cache maintenance instructions act on the target cache regardless of whether any stages of address translation are disabled, and regardless of the values of the memory attributes. However, if a stage of address translation is disabled, they use the flat address mapping for that translation stage.

TLB invalidate operations act on the target TLB regardless of whether any stage of address translation is disabled.

The value of HCR_EL2.DC affect some address translation instructions, see Address translation instructions, AT* on page D4-2139.

Behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:
- The IPA output from the stage 1 translation maps flat to the PA.
- The memory attributes and permissions from the stage 1 translation apply to the PA.

When both stages of address translation are disabled, see also Behavior of instruction fetches when all associated stages of translation are disabled.

Behavior of instruction fetches when all associated stages of translation are disabled

When EL3 is using AArch64, this section applies to:
- The Secure EL1&0 translation regime when stage 1 address translation is disabled in that regime.
- The Secure EL3 translation regime when stage 1 address translation is disabled in that regime.
- The EL2, or EL2&0, translation regime when stage 1 address translation is disabled in that regime
- The Non-secure EL1&0 translation regime, when both stages of address translation are disabled.

--- Note ---
- The behaviors in Non-secure state apply regardless of the Execution state that EL3 is using.
- When the value of HCR_EL2.DC is 1, then the behavior of the Non-secure EL1&0 translation regime is as if stage 1 translation is disabled and stage 2 translation is enabled, as described in Behavior when stage 1 address translation is disabled on page D4-2136.

In these cases, when execution is in AArch64 state, a memory location might be accessed as a result of an instruction fetch if either:
- The memory location is in the same block of memory as, or in the next contiguous block of memory to, an instruction that a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset.
- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
  - The last reset.
  - The last synchronization of instruction cache maintenance targeting the address of the branch instruction.

In this description, the blocks of memory referred to are of the size of the minimum implemented translation granule and are aligned to that size.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.
Note

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when all associated stages of address translation are disabled are located in blocks of the address space, of the translation granule size, that contain only memory that is tolerant to speculative accesses.
- Each block of the address space, of the translation granule size, that immediately follows a similar block that holds instructions that will be executed when all associated stages address translation are disabled, contains only memory that is tolerant to speculative accesses.

D4.2.10 Pseudocode description of VMSAv8-64 address translation

The following subsections outline a pseudocode description of the translation table walk:

- Definitions required for address translation.
- Performing the full address translation.
- Stage 1 translation.
- Stage 2 translation.
- Translation table walk.
- Support functions on page D4-2139.

Definitions required for address translation

In pseudocode, the result of a translation table lookup, in either Execution state, is returned in a TLBRecord structure. Memory data type definitions on page D3-2077 includes definitions of the Permissions and AddressDescriptor parameters.

Performing the full address translation

The function AArch64.FullTranslate() performs a full translation table walk. For any translation regime it performs a stage 1 translation for the supplied VA, and for the Non-secure EL1&0 translation regime it then performs a stage 2 translation of the returned address.

Stage 1 translation

The function AArch64.FirstStageTranslate() performs a stage 1 translation, calling the function AArch64.TranslationTableWalk(), described in Translation table walk, to perform the required translation table walk. However, if stage 1 translation is disabled, it calls the function AArch64.TranslateAddressS1Off() to set the memory attributes.

Stage 2 translation

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the IPA address space, and must be mapped to a PA by a stage 2 translation. Function AArch64.SecondStageWalk() performs this translation, by calling the AArch64.SecondStageTranslate() function. When called from AArch64.SecondStageWalk(), the AArch64.SecondStageTranslate() function performs a second stage translation, from IPA to PA, of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section.

Translation table walk

The function AArch64.TranslationTableWalk() returns the result, in the form of a TLBRecord, of a translation table walk made for a memory access from an Exception level that is using AArch64.
Support functions

In the translation table walk functions, the \texttt{WalkAttrDecode()} function determines the attributes for a translation table lookup.

The function \texttt{AArch64.S1AttrDecode()} decodes the attributes from a stage 1 translation table lookup.

The function \texttt{AArch64.CheckPermission()} checks the access permissions returned by a stage 1 translation table lookup, see \textit{Access permission checking} on page D3-2079.

The function \texttt{AArch64.CheckS2Permission()} checks the access permissions returned by a stage 2 translation table lookup.

The function \texttt{AddrTop()} returns the bit number of the most significant valid bit of a VA in the current translation regime. If EL1 is using AArch64 and EL0 is using AArch32 then an address from EL0 is zero-extended to 64 bits.

D4.2.11 Address translation instructions

Each of the ARMv8 instruction sets provides instructions that return the result of translating an input address, supplied as an argument to the instruction, using a specified translation stage or regime.

The available instructions only perform translations that are accessible from the Security state and Exception level at which the instruction is executed. That is:

- No instruction executed in Non-secure state can return the result of a Secure address translation stage.
- No instruction can return the result of an address translation stage that is controlled by an Exception level that is higher than the Exception level at which the instruction is executed.

\textit{Address translation instructions, AT*} summarizes the A64 address translation instructions.

See also \textit{A64 system instructions for address translation} on page C5-432.

Address translation instructions, AT*

The A64 assembly language syntax for address translation instructions is:

\begin{verbatim}
AT <operation>, <Xt>
\end{verbatim}

Where:

- \texttt{<operation>} is one of \texttt{S1E1R}, \texttt{S1E1RP}, \texttt{S1E1W}, \texttt{S1E0R}, \texttt{S1E0W}, \texttt{S12E1R}, \texttt{S12E1W}, \texttt{S12E0R}, \texttt{S12E0W}, \texttt{S1E2R}, \texttt{S1E2W}, \texttt{S1E3R}, or \texttt{S1E3W}.
- \texttt{<operation>} has a structure of \texttt{<stages><level><read|write><pan>}, where:
  - \texttt{<stages>} is one of:
    - S1 Stage 1 translation.
    - S12 Stage 1 translation followed by stage 2 translation.
  - \texttt{<level>} describes the Exception Level that the translation applies to. Is one of:
    - E0 EL0.
    - E1 EL1.
    - E2 EL2.
    - E3 EL3.
    - If \texttt{<level>} is higher than the current Exception Level, the instruction is UNDEFINED.
  - \texttt{<read|write>} is one of:
    - R Read.
    - W Write.
  - \texttt{<pan>} only available when ARMv8.2-ATS1E1 is implemented. Optional, but if present:
    - P determines action based on value of PSTATE.PAN.
    - Only permitted for \texttt{<stages>=S1 and <level>=E1}.
The address to be translated. No alignment restrictions apply for the address.

If EL2 is not implemented, the AT S1E2R and AT S1E2W instructions are UNDEFINED.

--- Note ---
If EL2 is not implemented but EL3 is implemented, the AT S1E++ instructions are not UNDEFINED, but behave the same way as the equivalent AT S1E++ instructions. This is consistent with the behavior if EL2 is implemented but stage 2 translation is disabled.

In each case, the address being translated is held in the 64-bit address argument register, Xt. If the address translation instruction uses a translation regime that is using AArch32, meaning it requires a VA of only 32 bits, then VA[63:32] is RES0.

If the address translation is successful, the resulting PA is returned in PAR_EL1.PA, and PAR_EL1.F is set to 0 to indicate that the translation was successful. Otherwise, see Synchronous faults generated by address translation instructions.

--- Note ---
The architecture provides a single PAR, PAR_EL1, that is used regardless of:
- The Exception level at which the instruction was executed.
- The Exception level that controls the stage or stages of translation used by the instruction.

For all of these instructions, the current context information determines which entries in TLB caching structures are used, and how the translation table walk is performed. However, it is IMPLEMENTATION DEFINED whether the Address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, ARM recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

If EL3 is implemented, then for instructions that apply to the EL1 or EL0 Exception level, SCR_EL3.NS determines the translation regime to which the instruction applies, as follows:

- SCR_EL3.NS == 0  Secure EL1&0 translation regime.
- SCR_EL3.NS == 1  Non-secure EL1&0 translation regime.

All relevant context information used for the translation depends on this determination.

When Non-secure EL1&0 stage 1 address translation is disabled, any AT S1E0*, AT S1E1*, AT S12E0*, or AT S12E1* address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR_EL2.DC bit as described in Behavior when stage 1 address translation is disabled on page D4-2136.

Executing AT S1E2R or AT S1E2W at EL3 with SCR_EL3.NS == 0 is UNDEFINED.

--- Note ---
AT S1E++ instructions at EL3 with SCR_EL3.NS == 0 are not UNDEFINED but behave the same way as the equivalent AT S1E++ instructions.

Synchronous faults generated by address translation instructions

The address translation instructions use the translation mechanism, and that mechanism can generate the following synchronous faults:
- Translation fault.
- Access flag fault.
- Permission fault.
- Domain fault, when translating using the AArch32 translation systems.
- Address size fault.
- TLB conflict fault.
- Synchronous External aborts during a translation table walk.
In addition:

- If the address translation instruction requires two stages of translation then these faults could arise from either stage 1 or stage 2.

- For a stage 1 translation for the Non-secure EL1&0 translation regime, the fault might be generated on the stage 2 translation of an address accessed as part of the stage 1 translation table walk, see Stage 2 fault on a stage 1 translation table walk on page D4-2197.

Except as described in this section, these faults are not taken as an exception for the address translation instructions, but instead the PAR_EL1.FST field holds the Fault status information. In these cases the PAR_EL1.PA field does not hold the output address of the translation.

The exceptions to this reporting the fault in PAR_EL1 are:

- Synchronous External aborts during a translation table walk are taken as a Data Abort exception. For an address translation instruction executed at a particular Exception level, if the synchronous External abort is generated on a stage 1 translation table walk, the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 1 translation table walk for a memory access from that Exception level would be taken.

  - If the synchronous External abort is generated on a stage 2 translation table walk then:
    - If the address translation instruction was executed at EL3, the synchronous Data Abort exception is taken to EL3.
    - If the address translation instruction was executed at EL2 or EL1, the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 2 translation table walk for a memory access from that Exception level would be taken.

In any case where the address translation instruction causes a synchronous Data Abort exception to be taken:

  - The PAR_EL1 is UNKNOWN.
  - The ESR_ELx of the target Exception Level of the exception indicates that the fault was due to a translation table walk for a cache maintenance instruction.
  - The FAR_ELx of the target Exception Level holds the VA for the translation request.

- For the AT S1E0* and AT S1E1* instructions executed from the Non-secure EL1 Exception level, if there is a synchronous stage 2 fault on a memory access made as part of the translation table walk then if the value of SCR_EL3.EA is 1 then a synchronous External abort on a stage 2 translation table walk is taken to EL3. In all other cases of a synchronous stage 2 fault on a memory access made as part of the translation table walk, the fault is taken as an exception to EL2, and:
  - PAR_EL1 is UNKNOWN
  - ESR_EL2 indicates that the fault occurred on a translation table walk, and that the operation that faulted was a cache maintenance instruction.
  - HPFAR_EL2 holds the IPA that faulted
  - FAR_EL2 holds the VA that the executing software supplied to the address translation instruction.

This fault can occur for any of the following reasons:

  - Stage 2 Translation fault.
  - Stage 2 Access fault.
  - Stage 2 Permission fault.
  - Stage 2 Address size fault.
  - Synchronous External abort on a stage 2 translation table walk.
Synchronization requirements of the address translation instructions

Where an instruction results in an update to a System register, as is the case with the AT * address translation instructions, explicit synchronization must be performed before the result is guaranteed to be visible to subsequent direct reads of the PAR_EL1.

---- Note ----

This is consistent with the AArch32 requirement, where the VA to PA translation instructions are executed as writes to the (coproc==0b1111) System register encoding space, and the effect of those writes to other registers require explicit synchronization before the result is guaranteed to be visible to subsequent instructions.
D4.3 VMSAv8-64 translation table format descriptors

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the ARMv8 translation table descriptor formats:

- VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats.
- ARMv8 translation table level 3 descriptor formats on page D4-2147.

Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-2148 then gives more information about the descriptor attribute fields, and Control of Secure or Non-secure memory access on page D4-2154 describe how the NS and NSTable together control whether a memory access from Secure state accesses the Secure memory map or the Non-secure memory map.

D4.3.1 VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats

In the VMSAv8-64 translation table format, the difference in the formats of the level 0, level 1 and level 2 descriptors is:

- Whether a Block descriptor is permitted.
- If a Block descriptor is permitted, the size of the memory region described by that entry.
- The maximum OA size, depending on whether ARMv8.2-LPA is implemented.

These differences depend on the translation granule, as follows:

**4KB granule** Level 0 translation tables do not support Block descriptors.

A block descriptor:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

The maximum OA size of a lookup is 48 bits.

**16KB granule** Level 0 and level 1 translation tables do not support Block descriptors.

A Block descriptor in a level 2 table describes the mapping of the associated 32MB input address range.

The maximum OA size of a lookup is 48 bits.

**64KB granule** Level 0 lookup is not supported.

Other properties depend on whether ARMv8.2-LPA is implemented:

**If ARMv8.2-LPA is implemented**

A block descriptor:

- In a level 1 table describes the mapping of the associated 4TB input address range.
- In a level 2 table describes the mapping of the associated 512MB input address range.

The maximum OA size of a lookup is 48 bits.

**If ARMv8.2-LPA is not implemented**

Level 1 translation tables do not support Block descriptors.

A Block descriptor in a level 2 table describes the mapping of the associated 512MB input address range.

The maximum OA size of a lookup is 48 bits.

When a lookup returns a Table descriptor, the OA is the next-level table address.
Figure D4-15 shows the ARMv8 level 0, level 1, and level 2 descriptor formats that provide 48-bit OAs:

![Figure D4-15  VMSAv8-64 level 0, level 1 and level 2 descriptor formats with 48-bit OAs](image)

With the 4KB granule size, for the level 1 descriptor n is 30, and for the level 2 descriptor, n is 21. With the 16KB granule size, for the level 2 descriptor, n is 25. With the 64KB granule size, for the level 2 descriptor, n is 29.

A level 0 Table descriptor returns the address of the level 1 table.
A level 1 Table descriptor returns the address of the level 2 table.
A level 2 Table descriptor returns the address of the level 3 table.

‡ When m is 12, the RES0 field shown for bits[(m-1):12] is absent.

Figure D4-16 VMSAv8-64 level 0, level 1 and level 2 descriptor formats with 48-bit OAs

In an implementation that includes ARMv8.2-LPA, when the 64KB granule is used, the Block and Table descriptors are redefined as Figure D4-16 shows:

![Figure D4-16 VMSAv8-64 level 1 and level 2 descriptor formats, 64KB granule with ARMv8.2-LPA](image)

For the level 1 descriptor n is 42, and for the level 2 descriptor n is 29.

---

**Note**

The effects on the Non-secure EL1 descriptors when ARMv8.1-HPD is enabled and HCR_EL2.[NV, NV1] == {1,1} are detailed in *Effect of HCR_EL2.[NV, NV1]* on page D4-2188.
Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Block  The descriptor gives the base address of a block of memory, and the attributes for that memory region.

1, Table  The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

Block descriptor

Gives the base address and attributes of a block of memory, as follows:

4KB translation granule

- For a level 1 Block descriptor, bits[47:30] are bits[47:30] of the output address. This output address specifies a 1GB block of memory.
- For a level 2 descriptor, bits[47:21] are bits[47:21] of the output address. This output address specifies a 2MB block of memory.

16KB translation granule

For a level 2 Block descriptor, bits[47:25] are bits[47:25] of the output address. This output address specifies a 32MB block of memory.

64KB translation granule

For a level 1 Block descriptor:

- If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the output address and bits[47:42] are bits[47:42] of the output address. This output address specifies a 4TB block of memory.
- If ARMv8.2-LPA is not implemented, there is no level 1 Block descriptor.

For a level 2 Block descriptor:

- If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the output address, and bits[47:29] are bits[47:29] of the output address. This output address specifies a 512MB block of memory.
- If ARMv8.2-LPA is not implemented, bits[47:29] are bits[47:29] of the output address. This output address specifies a 512MB block of memory.

In ARMv8.0, bits[63:52, 11:2] provide attributes for the target memory block. When ARMv8.1-TTHM is implemented, bits[63:51, 11:2] provide the attributes for the target memory block. For more information, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-2148.

--- Note ---

- In ARMv8.0, the position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the Page descriptors.
- When ARMv8.2-TTPBHA is implemented, hardware can use bits[62:59] of the Block descriptors for IMPLEMENTATION DEFINED purposes, see Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-2148.
Table descriptor

Gives the translation table address for the next-level lookup, as follows:

**4KB translation granule**

- Bits[47:12] are bits[47:12] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[11:0] of the table address are zero.

**16KB translation granule**

- Bits[47:14] are bits[47:14] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[13:0] of the table address are zero.

**64KB translation granule**

- Bits[47:16] are bits[47:16] of the address of the required next-level table, which is:
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
  - When ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] of the required next-level table.
- Bits[15:0] of the table address are zero.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-2148.

If the translation table defines the Non-secure EL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.
D4.3.2 ARMv8 translation table level 3 descriptor formats

For the 4KB granule size, each entry in a level 3 table describes the mapping of the associated 4KB input address range.

For the 16KB granule size, each entry in a level 3 table describes the mapping of the associated 16KB input address range.

For the 64KB granule size, each entry in a level 3 table describes the mapping of the associated 64KB input address range.

Figure D4-17 shows the ARMv8 level 3 descriptor formats.

![Figure D4-17 VMSAv8-64 level 3 descriptor format](image)

- Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

- Descriptor bit[1] identifies the descriptor type, and is encoded as:
  - 0, Reserved, invalid
    - Behaves identically to encodings with bit[0] set to 0.
    - This encoding must not be used in level 3 translation tables.
  - 1, Page
    - Gives the address and attributes of a 4KB, 16KB, or 64KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

**Page descriptor**

- Gives the output address of a page of memory, as follows:
  - 4KB translation granule
    - Bits[47:12] are bits[47:12] of the output address for a page of memory.
  - 16KB translation granule
  - 64KB translation granule
    - If ARMv8.2-LPA is implemented, bits[15:12] are bits[51:48] and bits[47:16] are bits[47:16] of the output address for a page of memory.
    - If ARMv8.2-LPA is not implemented, bits[47:16] are bits[47:16] of the output address for a page of memory.
Bits[63:52, 11:2] provide attributes for the target memory page, see Memory attribute fields in the VMSAv8-64 translation table format descriptors.

**Note**

- In ARMv8.0, the position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the level 0, level 1, and level 2 block descriptors.
- When ARMv8.1-TTHM is implemented, the position and contents of bits[63:51, 11:2] are identical to bits[63:51, 11:2] in the level 0, level 1, and level 2 block descriptors.
- When ARMv8.2-TTPBHA is implemented, hardware can use bits[62:59] of the Page descriptors for IMPLEMENTATION DEFINED purposes, see Memory attribute fields in the VMSAv8-64 translation table format descriptors.

For the Non-secure EL1&0 stage 1 translations, the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

**D4.3.3 Memory attribute fields in the VMSAv8-64 translation table format descriptors**

Memory region attributes on page D4-2174 describes the region attribute fields. The following subsections summarize the descriptor attributes as follows:

**Table descriptor**

Table descriptors for stage 2 translations do not include any attribute field. For a summary of the attribute fields in a stage 1 table descriptor, that define the attributes for the next lookup level, see Next-level attributes in stage 1 VMSAv8-64 Table descriptors.

**Block and page descriptors**

These descriptors define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:

- Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D4-2150
- Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors on page D4-2152.

**Next-level attributes in stage 1 VMSAv8-64 Table descriptors**

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the attributes for the next-level translation table access, and bits[58:51] are IGNORED:

Next-level descriptor attributes, stage 1 only

<table>
<thead>
<tr>
<th>63 62 61 60 59 58</th>
<th>51</th>
</tr>
</thead>
<tbody>
<tr>
<td>NSTable</td>
<td></td>
</tr>
<tr>
<td>APTable</td>
<td></td>
</tr>
<tr>
<td>UXNTable or XNTable †</td>
<td></td>
</tr>
<tr>
<td>PXNTable ‡</td>
<td></td>
</tr>
</tbody>
</table>

† UXNTable for a translation regime that can apply to execution at EL0, otherwise XNTable.
‡ RES0 for a translation regime that cannot apply to execution at EL0.

These attributes are:

**NSTable, bit[63]**

For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see Hierarchical control of Secure or Non-secure memory accesses on page D4-2154.

For memory accesses from Non-secure state, including all accesses in the EL2 or EL2&0 translation regime, this bit is RES0 and is ignored by the PE.
APTable, bits[62:61]
Access permissions limit for subsequent levels of lookup, see Hierarchical control of data access permissions on page D4-2159.

APTable[0] is RES0:

- In the EL2 translation regime.

  Note

  In an implementation that includes ARMv8.1-VHE, when the value of HCR_EL2.E2H is 1 the translation regime for memory accesses from EL2 is the EL2&0 translation regime. APTable[0] can be valid (not RES0) in the EL2&0 translation regime.

- In the EL3 translation regime.

  From ARMv8.1, when ARMv8.1-HPD is implemented, this field can be disabled. When the value of TCR_ELx.HPD{0} or TCR_ELx.HPD1 is 1:
  - The value of the corresponding APTable field is ignored by hardware, allowing the field to be used by software.
  - The behavior of the system is as if the value of the corresponding APTable field is 0.

  Note

  From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[61] is treated as 0 regardless of the actual value, see Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D4-2189.

UXNTable or XNTable, bit[60]
XN limit for subsequent levels of lookup, see Hierarchical control of instruction fetching on page D4-2163.
The naming of this field depends on whether stage 1 of the translation regime can support two VA ranges:

Stage 1 can support two VA ranges
This field is UXNTable, and determines whether execution at EL0 of instructions fetched from the region identified at a lower level of lookup permitted.

  Note

  PXNTable is the equivalent control of execution at a higher Exception level.

Stage 1 supports only one VA range
This field is XNTable.

From ARMv8.1, when ARMv8.1-HPD is implemented, this field can be disabled. When the value of TCR_ELx.HPD{0} or TCR_ELx.HPD1 is 1:
  - The value of the corresponding UXNTable field is ignored by hardware, allowing the field to be used by software.
  - The behavior of the system is as if the value of the corresponding UXNTable field is 0.

  Note

  From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[60] holds PXNTable, see Additional behaviors when HCR_EL2.NV == 1 and HCR_EL2.NV1 == 1 on page D4-2189.

PXNTable, bit[59]
PXM limit for subsequent levels of lookup, see Hierarchical control of instruction fetching on page D4-2163.

This field is valid only for a stage 1 translation that can support two VA ranges. It is RES0 for stage 1 translations that can support only one VA range.
From ARMv8.1, when ARMv8.1-HPD is implemented, this field can be disabled. When the value of TCR_ELx.HPD{0} or TCR_EL1.HPD1 is 1:

- The value of the corresponding PXNTable field is IGNORED by hardware, allowing the field to be used by software.
- The behavior of the system is as if the value of the corresponding PXNTable field is 0.

Note

From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[59] is RES0, see Additional behaviors when HCR_EL2.NV ==1 and HCR_EL2.NV1 == 1 on page D4-2189.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-6653. For more information about these fields see Other fields in the VMSAv8-64 translation table format descriptors on page D4-2178.

### Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 1 translation:

<table>
<thead>
<tr>
<th>Block attributes (stage 1)</th>
<th>Page attributes (stage 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 62</td>
<td>59 58</td>
</tr>
<tr>
<td>PBHA⁰</td>
<td>IGNORED</td>
</tr>
<tr>
<td>Reserved for software use</td>
<td></td>
</tr>
<tr>
<td>UXN or XN †</td>
<td></td>
</tr>
<tr>
<td>PXN ‡</td>
<td></td>
</tr>
<tr>
<td>Contiguous</td>
<td></td>
</tr>
<tr>
<td>DBM *</td>
<td></td>
</tr>
</tbody>
</table>

† IGNORED if ARMv8.2-TTPBHA is not implemented.
‡ UXN for a translation regime that can apply to execution at EL0, otherwise XN.
* RES0 for a translation regime that cannot apply to execution at EL0.

For a stage 1 descriptor, the attributes are:

**PBHA, bits[62:59]**

Page-based hardware attributes bits.

These bits are IGNORED when ARMv8.2-TTPBHA is not implemented.

When ARMv8.2-TTPBHA is implemented, each TCR_ELx has a control bit for each PBHA bit in the translation tables that it controls. When the value of that control bit is 1, and the value of the corresponding Hierarchical permission disables bit, TCR_ELx.HPD{n} is 1, hardware can use that PBHA bit for IMPLEMENTATION DEFINED purposes.

The TCR_ELx control bits for this feature are:

**For a translation regime that supports only a single VA range**

**HWU0nn** Controls whether Block or Page descriptor bit[nn] can be used by hardware.

These controls apply only when the value of TCR_ELx.HPD0 is 1.

**For a translation regime that can support two VA ranges**

**HWU0nn** For the translation tables indicated by TTBR0_ELx, controls whether Block or Page descriptor bit[nn] can be used by hardware.

These controls apply only when the value of TCR_ELx.HPD0 is 1.
**HWU1nn**  For the translation tables indicated by TTBR1_ELx, controls whether Block or Page descriptor bit[nn] can be used by hardware.

These controls apply only when the value of TCR_ELx.HPD1 is 1.

If ARMv8.2-TTPBHA is not implemented, then the TCR_ELx control bits are RAZ/WI.

**XN or UXN, bit[54]**

The Execute-never or Unprivileged execute-never field, see *Access permissions for instruction execution on page D4-2159.*

--- **Note** ---

From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[54] holds PXN, see *Additional behaviors when HCR_EL2.NV ==1 and HCR_EL2.NV1 == 1 on page D4-2189.*

**PXN, bit[53]**  The Privileged execute-never field, see *Access permissions for instruction execution on page D4-2159.*

This field is valid only when stage 1 of the translation regime can support two VA ranges. It is RES0 when stage 1 can support only one VA range.

--- **Note** ---

From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[53] is RES0, see *Additional behaviors when HCR_EL2.NV ==1 and HCR_EL2.NV1 == 1 on page D4-2189.*

**Contiguous, bit[52]**

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see *The Contiguous bit on page D4-2178.*

**DBM, bit[51]**  Dirty Bit Modifier, see *The dirty state bit on page D4-2165.*

**nG, bit[11]**  The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See *Global and process-specific translation table entries on page D4-2204.*

This field is valid only when stage 1 of the translation regime can support two VA ranges. It is RES0 when stage 1 can support only one VA range.

**AF, bit[10]**  The Access flag, see *The Access flag on page D4-2165.*

**SH, bits[9:8]**  Shareability field, see *Memory region attributes on page D4-2174.*

**AP[2:1], bits[7:6]**  Data Access Permissions bits, see *Memory access control on page D4-2155.*

--- **Note** ---

The ARMv8 translation table descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is valid only for stage 1 of a translation regime that can support two VA ranges. It is RES1 when stage 1 translations can support only one VA range.

--- **Note** ---

From ARMv8.3, in the Non-secure EL1 translation regime, when the value of HCR_EL2.{NV, NV1} == {1, 1}, bit[6] is treated as 0 regardless of its actual value, see *Additional behaviors when HCR_EL2.NV ==1 and HCR_EL2.NV1 == 1 on page D4-2189.*
NS, bit[5] Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in the Secure or Non-secure address map, see Control of Secure or Non-secure memory access on page D4-2154.

For memory accesses from Non-secure state, including all accesses in the EL2, or EL2&0, translation regime, this bit is RES0 and is ignored by the PE.

AttrIndx[2:0], bits[4:2] Stage 1 memory attributes index field, for the MAIR_ELx, see Stage 1 memory region type and Cacheability attributes on page D4-2175.

The definition of ignored means the architecture guarantees that the PE makes no use of the field, see IGNORED on page Glossary-6653. For more information about these fields see Other fields in the VMSAv8-64 translation table format descriptors on page D4-2178.

Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 2 translation:

Attribute fields for VMSAv8-64 stage 2 Block and Page descriptors

<table>
<thead>
<tr>
<th>Upper attributes</th>
<th>Lower attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>62</td>
</tr>
<tr>
<td>PBHA†</td>
<td>IGNORED</td>
</tr>
</tbody>
</table>

Reserved for use by a System MMU
Reserved for software use
XN[1:0]‡
Contiguous
DBM

‡ Bit[53] is RES0 if ARMv8.2-TTS2UXN is not implemented.
† Reserved for use by System MMU if ARMv8.2-TTPBHA is not implemented.
* RES0 if ARMv8.1-TTHM is not implemented.
For a stage 2 descriptor, the attributes are:

**PBHA, bits[62:59]**

Page-based hardware attributes bits.

These bits are IGNORED and reserved for System MMU use when ARMv8.2-TTPBHA is not implemented.

When ARMv8.2-TTPBHA is implemented, VTCR_EL2 has a control bit for each PBHA bit in the EL1&0 stage 2 translation tables. When the value of that control bit is 1, hardware can use the corresponding PBHA bit for IMPLEMENTATION DEFINED purposes.

If ARMv8.2-TTPBHA is not implemented, then the VTCR_EL2 control bits are RAZ/WI.

**XN[1:0], bits[54:53]**

The Execute-never field, see *Access permissions for instruction execution on page D4-2159.*

If ARMv8.2-TTS2UXN is not implemented, bit[53] is RES0.

**Contiguous, bit[52]**

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see *The Contiguous bit on page D4-2178.*

**DBM, bit[51]** . Dirty Bit Modifier, see *The dirty state bit on page D4-2165.*

**AF, bit[10]** . The Access flag, see *The Access flag on page D4-2165.*

**SH, bits[9:8]** . Shareability field, see *The stage 2 memory region attributes, EL1&0 translation regime on page D4-2176.*

**S2AP, bits[7:6]**

Stage 2 data Access Permissions bits, see *The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-2158.*

--- Note ---

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

---

**MemAttr, bits[5:2]**

Stage 2 memory attributes, see *The stage 2 memory region attributes, EL1&0 translation regime on page D4-2176.*

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see *IGNORED on page Glossary-6653.* For more information about these fields see *Other fields in the VMSAv8-64 translation table format descriptors on page D4-2178.*
D4.3.4 Control of Secure or Non-secure memory access

As this section describes, the NS bit in the translation table entries:

- For accesses from Secure state, if the translation table entry was held in secure memory, determines whether the access is to Secure or Non-secure memory.
- Is ignored by:
  - Accesses from Non-secure state.
  - Accesses from Secure state if the translation table entry was held in Non-secure memory.

In the VMSAv8-64 translation table format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, that affects accesses at lower levels of lookup, see Hierarchical control of Secure or Non-secure memory accesses.

The NS and NSTable bits are valid only for memory accesses from Secure state described by translation table descriptors that are fetched from Secure memory, and:

- In the translation table descriptors in a Non-secure translation table, the NS and NSTable bits are SBZ.
- Memory accesses from Non-secure state, including all accesses from EL2, ignore the values of these bits.

In the Secure translation regimes, for translation table descriptors that are fetched from Secure memory, the NS bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map, as follows:

- NS == 0  Access the Secure PA space.
- NS == 1  Access the Non-secure PA space.

For Non-secure translation regimes, and for translation table descriptors fetched from Non-secure memory, the corresponding bit is RES0 and is ignored by the PE. The access is made to Non-secure memory, regardless of the value of the bit.

Hierarchical control of Secure or Non-secure memory accesses

For VMSAv8-64 table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

- NSTable == 0  The defined table address is in the Secure PA space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.
- NSTable == 1  The defined table address is in the Non-secure PA space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:
  - The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.
  - The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if it is read from Non-secure memory. That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see Global and process-specific translation table entries on page D4-2204.

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.
D4.4 Memory access control

The access control fields in the translation table descriptors determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

• About access permissions.
• About PSTATE.PAN on page D4-2156.
• About PSTATE.UAO on page D4-2157.
• Data access permission controls on page D4-2157.
• Access permissions for instruction execution on page D4-2159.
• The Access flag on page D4-2165.
• The dirty state bit on page D4-2165.
• Software management of the Access flag on page D4-2165.
• Hardware management of the Access flag and dirty state on page D4-2165.
• Ordering of hardware updates to the translation tables on page D4-2172.
• Restriction on memory types for hardware updates on page tables on page D4-2172.
• Use of the Contiguous bit with hardware updates of the translation table entries on page D4-2173.

Note
This section describes the access controls for each of the translation regimes, and for each stage of translation in the Non-secure EL1&0 translation regime.

A translation applies to memory accesses from either:

• Only a single Exception level, for example the EL3 translation regime.
• EL0 and one higher Exception level, for example the EL1&0 translation regime.

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of the target memory region. These fields can be classified as address map control, access control, and region attribute fields. Control of Secure or Non-secure memory access on page D4-2154 describes the address map control, and Memory region attributes on page D4-2174 describes the other fields.

D4.4.1 About access permissions

The translation table descriptors include fields that define access permissions for data accesses and for instruction fetches. This section introduces those fields. In addition:

• System register controls can prevent execution from writable locations, see Preventing execution from writable locations on page D4-2164.

• For the effect of disabling a stage of address translation on the access permissions see The effects of disabling a stage of address translation on page D4-2136.

• From ARMv8.1, the PSTATE.PAN bit can affect the access permissions for privileged data accesses, see About PSTATE.PAN on page D4-2156.

• From ARMv8.2, the PSTATE.UAO bit can affect the access permissions for unprivileged instructions, see About PSTATE.UAO on page D4-2157.

Note
This section gives a general description of memory access permissions. In an implementation that includes EL2, software executing at EL1 in Non-secure state can see only the access permissions defined by the Non-secure EL1&0 stage 1 translations. However, software executing at EL2 can modify these permissions. This modification is invisible to the Non-secure software executing at EL1 or EL0.
The access permission bits control access to the corresponding memory region. The VMSAv8-64 translation table format:

- In stage 1 translations, uses AP[2:1] to define the data access permissions, see *The AP[2:1] data access permissions, for stage 1 translations* on page D4-2157.

  __Note__
  
  The description of the access permission field as AP[2:1] is for consistency with the VMSAv8-32 Short-descriptor translation table format, see *The VMSAv8-32 Short-descriptor translation table format* on page G4-4859. The VMSAv8-64 translation table format does not define an AP[0] bit.

- In stage 2 translations, uses S2AP[1:0] to define the data access permissions, see *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-2158.

- Uses the UXN, XN and PXN fields to define access controls for instruction fetches, see *Access permissions for instruction execution* on page D4-2159.

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation.

__Note__

In an implementation that includes EL2, each stage of the translation of a memory access made using the Non-secure EL1&0 translation regime has its own, independent, permission check.

### D4.4.2 About PSTATE.PAN

When the value of PSTATE.PAN is 1, any privileged data access from EL1 or EL2 to a virtual memory address that is accessible at EL0 generates a Permission fault.

When the value of PSTATE.PAN is 0, the translation system is the same as in ARMv8.0.

A corresponding PAN bit is added to SPSR_EL1, SPSR_EL2, and SPSR_EL3 for exception returns, and DSPSR_EL0 for entry to or exit from Debug state.

A new SPAN bit is added to SCTLR_EL1 and SCTLR_EL2, and applies when HCR_EL2.{E2H, TGE} == {1, 1}. The bit is used to control whether the PAN bit is set on an exception to EL1 or EL2.

The PAN bit has no effect on:

- Data Cache instructions other than DC ZVA.
- Address translation instructions, other than ATS1E1RP and ATS1E1wP when ARMv8.2-ATS1E1 is implemented.
- Unprivileged instructions, LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH, unless HCR_EL2.{E2H, TGE} == {1, 0}.
- Instruction accesses.

If access is disabled, then the access will give rise to a stage 1 Permission fault.

On an exception that is taken from AArch64 to AArch64, PSTATE.PAN is copied to SPSR_ELx.PAN.

On an exception return from AArch64:

- SPSR_ELx.PAN is copied to PSTATE.PAN, when the target Exception level is in AArch64.
- SPSR_ELx.PAN is copied to CPSR.PAN, when the target Exception level is in AArch32.

__Note__

- In Non-debug state, in AArch64 state:
  
  — Software can use an MSR PAN, #Imm4 or MSR PAN, Xt instruction to modify PSTATE.PAN, or an MRS Xt, PAN instruction to read PSTATE.PAN.
  
  — In Non-secure EL1, when HCR_EL2.{NV, NV1} == {1, 1}, PSTATE.PAN is treated as 0 for all purposes except reading the value of the bit.
D4.4 Memory access control

In Debug state, in AArch64 state, a debugger can use the DRPS instruction to modify PSTATE.PAN.

D4.4.3 About PSTATE.UAO

When the value of PSTATE.UAO is 1, a Load/Store unprivileged instruction executed at EL1, or executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} is subject to the memory access permissions that apply to the Exception level at which it is executed, rather than being subject to the EL0 access permissions. This means the Load/Store unprivileged instruction is subject to the same access permissions as the corresponding Load/Store register instruction. See Load/Store unprivileged on page C3-173 and Load/Store register on page C3-169.

When ARMv8.2-UAO is implemented and PSTATE.UAO is 0, it has no effect on the described behavior of any Load/Store unprivileged instruction.

A corresponding UAO bit is added to SPSR_EL1, SPSR_EL2, and SPSR_EL3 for exception returns, and DSPSR_EL0 for entry to or exit from Debug state.

On an exception that is taken from AArch64 state to AArch64 state, PSTATE.UAO is copied to SPSR_ELx.UAO and then set to 0.

On an exception that is taken from AArch32 state to AArch64 state:

- PSTATE.UAO is set to 0.
- SPSR_ELx.UAO is set to 0.

On an exception return from AArch64 state to AArch64 state, SPSR_ELx.UAO is copied to PSTATE.UAO.

Note

- In Non-debug state, in AArch64 state, software can use an MSR UAO, #Imm4 or MSR UAO, Xt instruction to modify PSTATE.PAN, or an MSR Xt, UAO instruction to read PSTATE.UAO.
- In Debug state, in AArch64 state, a debugger can use the DRPS instruction to modify PSTATE.UAO.

D4.4.4 Data access permission controls

The following subssections describe the data access permission controls:

- The AP[2:1] data access permissions, for stage 1 translations.
- The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-2158.
- Hierarchical control of data access permissions on page D4-2159.

The AP[2:1] data access permissions, for stage 1 translations

In VMSAv8-64, for a translation regime that applies to both EL0 and a higher Exception level, the AP[2:1] bits control the stage 1 data access permissions, and:

- AP[2] Selects between read-only and read/write access.
- AP[1] Selects between Application level (EL0) control and the higher Exception level control.

This provides four permission settings for data accesses:

- Read-only at all levels.
- Read/write at all levels.
- Read-only at the higher Exception level, no access by software executing at EL0.
- Read/write at the higher Exception level, no access by software executing at EL0.

Note

In an implementation that does not include ARMv8.1-VHE, the only translation regime that applies to EL0 and a higher Exception level is the EL1&0 translation regime. In an implementation that includes ARMv8.1-VHE, the EL2&0 translation regime applies to both Non-secure EL0 and EL2 when the value of HCR_EL2.{E2H, TGE} is {1, 1}.
For translation regimes that apply only to accesses from a single Exception level, AP[2] determines the stage 1 data access permissions, and AP[1] is RES1, meaning it is ignored by hardware and is treated as if it is 1.

Table D4-29 shows the meaning of the AP[2:1] field for stage 1 of a translation regime that applies to both EL0 and a higher Exception level. In this table, an entry of None indicates that any access from that Exception level faults.

### Table D4-29 Data access permissions for stage 1 translations that applies to EL0 and a higher Exception level

<table>
<thead>
<tr>
<th>AP[2:1]</th>
<th>Access from higher Exception level</th>
<th>Access from EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Read/write</td>
<td>None</td>
</tr>
<tr>
<td>01</td>
<td>Read/write</td>
<td>Read/write</td>
</tr>
<tr>
<td>10</td>
<td>Read-only</td>
<td>None</td>
</tr>
<tr>
<td>11</td>
<td>Read-only</td>
<td>Read-only</td>
</tr>
</tbody>
</table>

For the Non-secure EL1&0 translation regime:

- The stage 2 translation also defines data access permissions, see The S2AP data access permissions, Non-secure EL1&0 translation regime.

- When both stages of translation are enabled, Combining the stage 1 and stage 2 data access permissions on page D4-2180 describes how these permissions are combined.

Table D4-30 shows the effect of the AP[2] field for stage 1 of a translation regime that applies to only a single Exception level.

### Table D4-30 Data access permissions for stage 1 translations that apply to only a single Exception level

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Read/write</td>
</tr>
<tr>
<td>1</td>
<td>Read-only</td>
</tr>
</tbody>
</table>

**The S2AP data access permissions, Non-secure EL1&0 translation regime**

In the Non-secure EL1&0 translation regime, when stage 2 address translation is enabled, the S2AP field in the stage 2 translation table descriptors define the data access permissions as Table D4-31 shows. In this table, an entry of None indicates that any access generates a Permission fault.

### Table D4-31 Data access permissions for stage 2 of the Non-secure EL1&0 translation regime

<table>
<thead>
<tr>
<th>S2AP</th>
<th>Access from Non-secure EL1 or Non-secure EL0</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>None</td>
</tr>
<tr>
<td>01</td>
<td>Read-only</td>
</tr>
<tr>
<td>10</td>
<td>Write-only</td>
</tr>
<tr>
<td>11</td>
<td>Read/write</td>
</tr>
</tbody>
</table>

The S2AP access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined by AP[2:1], see Combining the stage 1 and stage 2 data access permissions on page D4-2180.
Hierarchical control of data access permissions

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the data access permissions.

--- Note ---

Similar hierarchical controls apply to instruction fetching, see Hierarchical control of instruction fetching on page D4-2163.

However, in an implementation that includes ARMv8.1-HPD, when the value of a TCR_ELx.HPD{0} field is 1, or the value of the TCR_ELx.HPD1 field is 1, the hierarchical control of data access permissions is disabled for the translation stage controlled by that TCR_ELx, and the information in this subsection does not apply.

The restrictions apply only to subsequent levels of lookup for the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table D4-32 shows. As stated in the table footnote, for a translation regime that applies to only a single Exception level, APTable[0] is RES0, meaning it is ignored by the hardware.

<table>
<thead>
<tr>
<th>APTable[1:0]</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect on permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>01</td>
<td>Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>10</td>
<td>Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>11</td>
<td>Regardless of permissions in subsequent levels of lookup:</td>
</tr>
<tr>
<td></td>
<td>• Write access not permitted, at any Exception level.</td>
</tr>
<tr>
<td></td>
<td>• Read access not permitted at EL0.</td>
</tr>
</tbody>
</table>

--- Note ---

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The VMSAv8-64 provides APTable[1:0] control only for stage 1 translations. The corresponding bits are RES0 in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

D4.4.5 Access permissions for instruction execution

Execute-never controls determine whether instructions can be executed from a memory region. These controls are:

UXN, Unprivileged execute-never, stage 1 only

Descriptor bit[54], defined as UXN only for stage 1 of any translation regime for which stage 1 translation can support two VA ranges.
This field applies only to execution at EL0. A value of 0 indicates that this control permits execution.

**XN, Execute-never**

Descriptor bit[54], defined as XN for:
- Stage 1 of any translation regime for which the stage 1 translation can support only a single VA range.
- Stage 2 translations when **ARMv8.2-TTS2UXN** is not implemented.

--- Note ---

**XN[1:0], Execute-never, stage 2 only** describes the stage 2 control when **ARMv8.2-TTS2UXN** is implemented.

---

This field applies to execution at any Exception level to which the stage of translation applies. A value of 0 indicates that this control permits execution.

**PXN, Privileged execute-never, stage 1 only**

Descriptor bit[53], used only for stage 1 of any translation regime for which stage 1 translation can support two VA ranges.
- For stage 1 of a translation regime for which the stage 1 translation supports only a single VA range the stage 1 descriptors define a PXN field that is RES0, meaning it is ignored by hardware.

This field applies only to execution at an Exception level higher than EL0. A value of 0 indicates that this control permits execution.

**XN[1:0], Execute-never, stage 2 only**

Descriptor bits[54:53], defined as XN[1:0] for:
- Stage 2 translations when **ARMv8.2-TTS2UXN** is implemented.

Table D4-33 shows the operation of this control.

<table>
<thead>
<tr>
<th>XN[1]</th>
<th>XN[0]</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>The stage 2 control permits execution at EL1 and EL0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>The stage 2 control does not permit execution at EL1, but permits execution at EL0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>The stage 2 control does not permit execution at EL1 or EL0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The stage 2 control permits execution at EL1, but does not permit execution at EL0</td>
</tr>
</tbody>
</table>

--- Note ---

For stage 2 translations when **ARMv8.2-TTS2UXN** is not implemented, descriptor bit[53] is RES0, meaning it is ignored by hardware.

--- Note ---

In an implementation that does not include **ARMv8.1-VHE**, the only translation regime for which stage 1 translation can support two VA ranges is the EL1&0 translation regime. In an implementation that includes **ARMv8.1-VHE:**

- When the value of **HCR_EL2.E2H** is 1, **TCR_EL2** controls the EL2&0 translation regime, and this regime:
  - Supports two VA ranges, corresponding to **TTBR0_EL2** and **TTBR1_EL2**.
  - Always supports both UXN and PXN fields.
Memory accesses from Non-secure EL0 are translated using the EL2&0 translation regime only when the value of HCR_EL2.{E2H, TGE} is \{1, 1\}.

Table D4-33 on page D4-2160 shows the operation of the stage 2 XN[1:0] control, and for each single-bit execute-never field a value of 1 indicates that, at an exception level to which the control applies, instructions cannot be executed from the target memory region. In addition:

- For a translation regime that applies to EL0 and a higher Exception level, if the value of the AP[2:1] bits is 0b01, permitting write access from EL0, then the PXN field is treated as if it has the value 1, regardless of its actual value.
- In a translation regime with two stages of translation, a region is execute-never if execution is not permitted by the value of the applicable execute-never field in one or both of:
  - The stage 1 translation table descriptor.
  - The stage 2 translation table descriptor.
- For each translation regime, if the value of the corresponding SCTLR_ELx.WXN field is 1 then any memory region that is writable is treated as XN, regardless of the value of the corresponding UXN, XN, or PXN field. For more information, see Preventing execution from writable locations on page D4-2164.
- The SCR_EL3.SIF bit prevents execution in Secure state of any instruction fetched from Non-secure memory, see Restriction on Secure instruction fetch on page D4-2165.

The execute-never controls apply to speculative instruction fetching, meaning speculative instruction fetch from a memory region that is execute-never at the current Exception level is prohibited.

Note

- Although the execute-never controls apply to speculative fetching, on a speculative instruction fetch from an execute-never location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an execute-never location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
- The software that defines a translation table must mark any region of memory that is read-sensitive as execute-never, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as execute-never. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.
- When no stage of address translation for the translation regime is enabled, memory regions cannot have UXN, XN, or PXN attributes assigned. Behavior of instruction fetches when all associated stages of translation are disabled on page D4-2137 describes how disabling all stages of address translation affects instruction fetching.

The following subsubsections give more information about the data access permission controls:

- Stage 1 instruction access and execution permissions on page D4-2162.
- Stage 2 instruction execution permissions on page D4-2163.
- Hierarchical control of instruction fetching on page D4-2163.
- Preventing execution from writable locations on page D4-2164.
- Restriction on Secure instruction fetch on page D4-2165.
Stage 1 instruction access and execution permissions

Table D4-34 and Table D4-35 on page D4-2163 include the AP[2:1] read and write permissions shown in Table D4-29 on page D4-2158 and Table D4-30 on page D4-2158. These permissions are shown as:

- R. Indicates Read permission granted.
- W. Indicates Write permission granted.

Table D4-34 shows the stage 1 access permissions for instruction execution when using a translation regime that applies to EL0 and a higher Exception level.

</tbody>
</table>

a. Where ELx is the higher Exception level to which the translation regime applies.
b. Not executable because of the SCTLR_ELx.WXN control, because region is writable at ELx.

Note

The Access permissions for an AArch64 translation regime that applies to only a single Exception level are consistent with the following fields in the translation table entries being treated as shown:

- AP treated as RES1.
- APTable[0] treated as RES0.
- PXN treated as RES0.
- PXNTable treated as RES0.

Stage 2 instruction execution permissions

For the Non-secure EL1&0 stage 2 translation, the XN fields in the stage 2 translation table descriptors control the execution permission, and this control is completely independent of the S2AP access permissions:

- When ARMv8.2-TTS2UXN is not implemented the stage 2 XN field is a 1-bit field that applies to execution at both EL0 and EL1, see XN, Execute-never on page D4-2160.
- When ARMv8.2-TTS2UXN is implemented the stage 2 XN field is a 2-bit field that provides independent control of execution from EL0 and execution from EL1, see XN[1:0], Execute-never, stage 2 only on page D4-2160.

See also Combining the stage 1 and stage 2 instruction execution permissions on page D4-2180.

Hierarchical control of instruction fetching

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the instruction fetching controls.

Note

Similar hierarchical controls apply to data accesses, see Hierarchical control of data access permissions on page D4-2159.

However, in an implementation that includes ARMv8.1-HPD, when the value of a TCR_ELx.HPD{0} field is 1, or the value of the TCR_ELx.HPD1 field is 1, the hierarchical control of instruction fetching is disabled for the translation stage controlled by that TCR_ELx, and the information in this subsection does not apply.
The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- **UXNTable** or **XNTable** restricts the execute-never control:
  - When the value of the **XNTable** bit is 1, the **UXN** bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of the **UXNTable** bit is 1, the **XN** bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of a **UXNTable** or **XNTable** bit is 0 the bit has no effect.

- For a translation regime that applies to EL0 and a higher Exception level, **PXNTable** restricts the **PXN** control:
  - When the value of **PXNTable** is 1, the **PXN** bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When the value of **PXNTable** is 0 it has no effect.

--- **Note**

The **UXNTable**, **XNTable**, and **PXNTable** settings are combined with the **XN**, **UXN**, and **PXN** bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The **UXNTable**, **XNTable**, and **PXNTable** controls are provided only for stage 1 translations. The corresponding bits are **RES0** in the stage 2 translation table descriptors.

The effect of **UXNTable**, **XNTable**, or **PXNTable** applies to earlier entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to **UXNTable**, **XNTable**, or **PXNTable** requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

**Preventing execution from writable locations**

ARMv8 provides control bits that, when corresponding stage 1 address translation is enabled, force writable memory to be treated as **XN**, **PXN**, or **UXN**, regardless of the value of the **XN**, **PXN**, or **UXN** bit:

- For a translation regime that applies to EL0 and a higher Exception value, when the value of the applicable **SCTLR_ELx.WXN** field is 1:
  - All regions that are writable from EL0 at stage 1 of the address translation are treated as **XN**.
  - All regions that are writable from EL1 at stage 1 of the address translation are treated as **PXN**.

- For a translation regime that applies to only a single Exception level, when the value of the applicable **SCTLR_ELx.WXN** field is 1, all regions that are writable at stage 1 of the address translation are treated as **UXN**.

--- **Note**

- The **SCTLR_ELx.WXN** controls are intended to be used in systems with very high security requirements.
- Setting a WXN field to 1 changes the interpretation of the translation table entry, overriding a zero value of a **XN**, **UXN**, or **PXN** field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN to remain static in normal operation. In particular, it is **IMPLEMENTATION DEFINED** whether TLB entries associated with a particular **VMID** reflect the effect of the values of these fields. This means that any change of these fields without a corresponding change of VMID might require synchronization and TLB invalidation, as described in **TLB maintenance requirements and the TLB maintenance instructions** on page D4-2207.
Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR_EL3.SIF. When the value of this bit is 1, and execution is using the EL3 translation regime or the Secure EL1&0 translation regime, any attempt to execute an instruction fetched from Non-secure physical memory causes a Permission fault. TLB entries might reflect the value of this bit, and therefore any change to the value of this bit requires synchronization and TLB invalidation, as described in TLB maintenance requirements and the TLB maintenance instructions on page D4-2207.

In an implementation that does not implement EL3, the Effective value of this bit is 0.

D4.4.6 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0.

The AF bit in the translation table descriptors is the Access flag.

In ARMv8.0, the Access flag is managed by software as described in Software management of the Access flag.

From ARMv8.1, the Access flag can be managed by hardware as described in Hardware management of the Access flag on page D4-2166.

Note
The support for hardware management of the Access flag applies only to the VMAv8-64 translation regimes.

D4.4.7 The dirty state bit

The dirty state bit indicates whether a page or section of memory is modified.

The DBM bit in the translation table descriptors is the dirty state bit.

The dirty state bit can be managed by hardware as described in Hardware management of dirty state on page D4-2167.

D4.4.8 Software management of the Access flag

ARMv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of Access flag is 0.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

Note
If a system incorporates components that can autonomously update translation table entries that are shared with the ARM PE, then the software must be aware of the possibility that such components can update the access flag autonomously.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

D4.4.9 Hardware management of the Access flag and dirty state

ARMv8.1 introduces the following optional features that perform hardware updates to the translation tables:

- Hardware management of the Access flag on page D4-2166.
- Hardware management of dirty state on page D4-2167.
The support for hardware management of the Access flag and dirty state is identified by the feature ARMv8.1-TTHM.

When the hardware management of the Access flag is enabled, in situations where, without this feature, an Access flag fault would be generated, the hardware instead performs an atomic read-modify-write of the appropriate translation table descriptor to update the Access flag from 0 to 1.

When the hardware management of dirty state is enabled, if the Block or Page descriptor in a translation table indicates that a data access does not have write permission, then in situations where, without this feature, a data access would generate a Permission fault only because of this lack of write permission, the hardware checks the value of the DBM field in the Block or Page descriptor. If this field is 1, then instead of generating a Permission fault, the hardware performs an atomic read-modify-write of the translation table descriptor, to change the value of the bit that prohibits the write access.

It is permissible, but not required, that a stage 2 permission failure on the stage 1 translation table walk has priority over the stage 1 abort generated by the stage 1 translation table entry if all the following are true:

- Stage 1 hardware updating of either access or dirty information is enabled.
- A stage 1 translation table entry results in the stage 1 translation table entry having the access or dirty bit updated.
- The stage 1 translation table entry has stage 2 read permission but not stage 2 write permission.
- The stage 1 translation entry generates an abort (which might be one of an address size fault, an alignment fault caused by memory type or a permission fault).

**Hardware management of the Access flag**

Hardware management of the Access flag is enabled, for the corresponding stage of address translation, by the following configuration fields:

**For stage 1 translations**
- `TCR_EL1.HA`
- `TCR_EL2.HA`
- `TCR_EL3.HA`

**For stage 2 translations**
- `VTCR_EL2.HA`

Implementations are not required to support the hardware management of the Access flag. If ARMv8.1-TTHM is not supported, then the HA bit in `TCR_EL1, TCR_EL2, TCR_EL3, and VTCR_EL2` is `RES0`.

When the value of a configuration bit, HA, is 1, then when a memory access is made using a translation table Block or Page descriptor from the corresponding stage of address translation:

- The PE sets the value of the Access flag to 1 in the translation table descriptor in memory, in a coherent manner, by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  - The descriptor does not generate a Permission fault or an Alignment fault based on the memory type.
  - If the hardware update mechanism was disabled or not implemented, the access would have generated an Access flag fault.

  When the PE updates the Access flag in this way no Access flag fault is generated.

- It is **CONSTRAINED UNPREDICTABLE** whether the PE sets the value of the Access flag in the translation table entry in memory to 1, in a coherent manner, by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  - The descriptor generates a Permission fault or an Alignment fault based on the memory type.
  - If the hardware update mechanism was disabled or not implemented, the access would have generated an Access flag fault.

This means that the value of the Access flag becomes **UNKNOWN** if the above conditions are all true.
The Access flag might be set to 1 as a result of speculative accesses by the PE.

--- Note ---

A consequence of the architectural rules for translation table accesses is that the architecture requires that for any translation to which an architecturally executed memory access occurs, the Access flag is set to 1, except as indicated in Using break-before-make when updating translation table entries on page D4-2208. However, because the architecture permits speculative accesses, the Access flag is permitted to be set to 1, even if there is no architecturally executed memory accesses by the processor.

--- Note ---

When hardware updating of the Access flag is enabled, each stage of translation is treated independently. This means that a single memory access can cause a hardware update to either or both:

- The stage 1 Access flag.
- The stage 2 Access flag.

--- Note ---

Since speculative accesses are permitted to update the Access flags, it is permissible for:

- The stage 1 Access flag for a translation of a virtual address to be updated in situations where the stage 2 translation of the associated intermediate physical address that is returned by the stage 1 of the virtual address does not permit access.
- The stage 2 Access flag for a translation of an intermediate physical address to be updated in situations where the stage 1 translation of the associated virtual address which returned that intermediate physical address does not permit access.

---

An address translation instruction for an address is permitted, but not required, to set the Access flag in the translation table entries for that address. Correspondingly, it is IMPLEMENTATION DEFINED whether such an instruction can generate a Data Abort if the Access flag for a stage of translation is updated to be set.

When hardware updates of the Access flag are enabled for a stage of translation an address translation instruction that uses that stage of translation will not report that the address will give rise to an Access flag fault in the PAR, and the result in PAR will be as if the value of the Access flag in the translation table entries for that address was 1.

**Hardware management of dirty state**

The hardware management of dirty state mechanism can only be enabled if hardware management of the Access flag is enabled. For information on the hardware management of the Access flag, see *Hardware management of the Access flag* on page D4-2166.

--- Note ---

The hardware management of dirty state mechanism uses:

- In a stage 1 translation table access, the AP[2] bit in conjunction with the DBM bit in the translation table descriptors.
- In a stage 2 translation table access, the S2AP[1] bit in conjunction with the DBM bit in the translation table descriptors.

---

Hardware management of dirty state is enabled, for the corresponding stage of address translation, by the following configuration fields:

**For stage 1 translations**

- TCR_EL1.HD.
- TCR_EL2.HD.
- TCR_EL3.HD.

**For stage 2 translations**

VTCR_EL2.HD.
Implementations are not required to support the dirty state mechanism. If this mechanism is not supported, then the HD bit in TCR_EL1, TCR_EL2, TCR_EL3, and VTCR_EL2 is RES0.

When hardware management of dirty state is enabled, and a memory access is made using a translation table Block or Page descriptor:

- For a stage 1 address translation, if the value of the TCR_ELx.HD field corresponding to the address translation is 1, then the PE sets AP[2] to 0 in the translation descriptor in memory, in a coherent manner by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  - The value of the DBM field in the descriptor is 1.
  - If the hardware update mechanism was disabled or not implemented, the access using this descriptor would have generated a Permission fault only because the value of the AP[2] field is 1, indicating that the access does not have write permission.

When the PE updates AP[2] in this way no Permission fault is generated because of the value of the AP[2] field.

- For a stage 2 address translation, if the value of the VTCR_EL2.HD field is 1, then the PE sets S2AP[1] to 1 in the translation descriptor in memory, in a coherent manner by an atomic read-modify-write of the translation table descriptor, if both of the following conditions are true:
  - The value of the DBM field in the descriptor is 1.
  - If the hardware update mechanism was disabled or not implemented, the access using this descriptor would have generated a Permission fault only because the value of the S2AP[1] field is 0, indicating that the access does not have write permission.

When the PE updates S2AP[1] in this way no Permission fault is generated because of the value of the S2AP[1] field.

**Note**

The PE that does the atomic update of the translation table descriptor is expected to ensure that any cached copy of that translation table descriptor for that PE is similarly updated, or removed from the TLB, so that multiple writes from the same thread on the same PE do not lead to multiple updates to the table. This is only a performance expectation.

If, for a write access, the PE finds that a cached copy of the descriptor in a TLB had the DBM bit set to 1 and the AP[2] or S2AP[1] bit set to the value that forbids writes, then the PE must check that the cached copy is not stale with regard to the descriptor entry in memory, and if necessary perform an atomic read-modify-write update of the descriptor in memory. This applies if the cached copy of the descriptor in a TLB is either:

- A stage 1 descriptor in which DBM has the value 1 and AP[2] has the value 1.
- A stage 2 descriptor in which DBM has the value 1 and S2AP[1] has the value 0.

**Note**

ARM expects that, in many implementations, any atomic update of a translation table entry required by the dirty state management mechanism will cause a translation table walk.

For the hardware updating of the AP[2] and S2AP[1] bits, each translation stage is treated independently. This means a single memory access can update either or both of:

- The stage 2 S2AP[1] bit.

The architecture does not permit updates to AP[2] and S2AP[1] by the hardware management of dirty state mechanism to occur as a result of speculative accesses by the PE that are not performed architecturally, except that for translation table entries for which the value of DBM is 1:

- A non-speculative access that passes its stage 1 permissions check can update AP[2] and subsequently encounter a stage 2 fault.
Note
This update of AP[2] is permitted even if the transaction subsequently encounters a stage 2 Translation fault or a Permission fault. This avoids a need to update both AP[2] and S2AP[1] as a single atomic update.

- A non-speculative access that generates an Alignment fault only because the memory type accessed is Device memory by a stage of translation can update AP[2] or S2AP[1] of that stage of translation if the memory access would have updated that translation table bit had the memory access not generated the Alignment fault.

- If the stage 2 hardware management of dirty state mechanism is enabled, the S2AP[1] field of a stage 2 translation table entry that is translating a stage 1 translation table without generating a stage 2 MMU fault:
  - Is updated from 0 to 1 as a result of a speculative update of the Access flag in an entry of that stage 1 translation table.
  - Is permitted to be updated speculatively from 0 to 1 as a result of performing a translation table walk using that stage 1 translation table, even if the entry in the stage 1 translation table is not updated. The speculative update is permitted to generate a synchronous External abort or an IMPLEMENTATION DEFINED abort caused by the memory type not supporting an atomic read-modify-write.

Note
This applies even if the stage 1 translation table contains entries that are not the final level entries and therefore would not be updated. This relaxation avoids the hardware complexity of having to detect whether the stage 1 entry is a final level entry before deciding to set the stage 2 dirty state information.

- If an instruction that generates more than one single-copy atomic memory access has a fault on some, but not all, of those memory accesses, then AP[2] and S2AP[1] bits associated with accesses from that instruction, which do not fault are permitted to be updated if the associated hardware update of dirty state mechanism is enabled.

For a Block or Page translation table descriptor for which the AF bit is 0, the DBM bit is 1, and either the value of the stage 1 AP[2] bit is 1 or the value of the stage 2 S2AP[1] bit is 0, both AF can be set to 1, and either AP[2] set to 0 or S2AP[1] set to 1, in a single atomic read-modify-write operation, as a result of an attempted write to a memory location that uses the translation table entry.

Implications of enabling the dirty state management mechanism
This subsection describes behaviors that result from having the dirty state management mechanism enabled for a particular stage of address translation.

For the final level of lookup in a stage 1 translation:

In the EL3 translation regime
The OA of the lookup is treated as writable if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2] is 1.
- In the descriptor for every higher level of lookup, the value of APTable[1] is 0.

In this case, if the value of SCTLR_EL3.WXN is 1 then the OA is treated as Execute-never.

In the EL2 or EL2&0 translation regime, when the value of HCR_EL2.{E2H, TGE} is not \{1, 1\}

Note
When the value of HCR_EL2.E2H is 1, TCR_EL2 controls the EL2&0 translation regime, and otherwise it controls the EL2 translation regime.

The OA of the lookup is treated as writable if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2] is 1.
In the descriptor for every higher level of lookup the value of APTable[1] is 0.
In this the value of SCTLR_EL2.WXN is 1 then the OA is treated as Execute-never.
In addition, if the value of HCR_EL2.E2H is 1, the OA is treated as Privileged execute-never if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1]
is 0b11.
- In the descriptor for every higher level of lookup, the value of APTable[1:0] is 0b00.

Note
When the value of HCR_EL2.{E2H, TGE} is not {1, 1}, memory accesses from EL0 do not use the EL2, or EL2&0, translation regime.

In the EL2&0 translation regime, when the value of HCR_EL2.{E2H, TGE} is {1, 1}
The OA of the lookup is treated as writable at EL2 and EL0, Privileged execute-never, if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
- In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b00.
In this case, if the value of SCTLR_EL2.WXN is 1 then the OA is also treated as Unprivileged execute-never.

The OA of the lookup is treated as writable at EL2 but not writable at EL0 if either:

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b10.
  - In at least one of the descriptors for higher levels of lookup the value of APTable[1:0] is 0b01.
In this case, if the value of SCTLR_EL2.WXN is 1 then the OA is treated as Privileged execute-never.

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
  - In at least one of the descriptors for higher levels of lookup the value of APTable[1:0] is 0b01.
In this case, if the value of SCTLR_EL2.WXN is 1 then the OA is treated as Privileged execute-never.

In the EL1&0 translation regime
The OA of the lookup is treated as writable at EL1 and EL0, Privileged execute-never, if all of the following conditions apply:

- In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
- In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b00.
In this case, if the value of SCTLR_EL1.WXN is 1 then the OA is treated as Unprivileged execute-never.

The OA of the lookup is treated as writable at EL1 but not writable at EL0 if either:

- Both:
  - In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b11.
  - In at least one of the descriptors for higher levels of lookup the value of APTable[1:0] is 0b01.
In this case, if the value of SCTLR_EL1.WXN is 1 then the OA is treated as Privileged execute-never.
• Both:
  — In the descriptor for the final level of lookup, the value of DBM is 1 and the value of AP[2:1] is 0b10.
  — In the descriptor for every higher level of lookup the value of APTable[1:0] is 0b0x.
  In this case, if the value of SCTLR_EL1.WXN is 1 then the OA is treated as Privileged execute-never.

The OA of a translation table entry where the DBM bit is 1, and the stage 1 AP[2] bit is 1 or the stage 2 S2AP[1] bit is 0, is treated as writable:

• For data cache invalidation instructions that require write permission, that is for the DC IVAC instruction.
• For address translation instructions that require write permission, that is for the AT S1E0W, AT S1E1W, AT S1E0W, AT S1E1W, AT S1E2W, and AT S1E3W instructions.

Cache invalidation and address translation instructions never cause the stage 1 AP[2] bit or the stage 2 S2AP[1] bit in the translation table entry to be updated.

For a Store-Exclusive instruction to a memory location for which the DBM bit is 1 and the stage 1 AP[2] bit is 1, if the Store-Exclusive fails because the Exclusives monitor is not in the exclusive state, it is IMPLEMENTATION DEFINED whether the AP[2] bit in the translation table is updated.

For a Store-Exclusive instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, if the Store-Exclusive fails because the Exclusives monitor is not in the Exclusive access state, it is IMPLEMENTATION DEFINED whether the S2AP[1] bit in the translation table is updated.

For a store to a memory location for which the DBM bit is 1, and the stage 1 AP[2] bit is 1, if the Store-Exclusive fails because the Exclusives monitor is not in the exclusive state, it is IMPLEMENTATION DEFINED whether the AP[2] bit in the translation table is updated:

• If the memory location generates a synchronous External abort on a write for a store to a memory location.
• If the memory location generates a watchpoint on a write.

For a store to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, it is IMPLEMENTATION DEFINED whether the S2AP[1] bit in the translation table is updated:

• If the memory location generates a synchronous External abort on a write for a store to a memory location.
• If the memory location generates a watchpoint on a write.

In the event of a PE setting the stage 1 AP[2] bit to 0, it is not required that all associated entries are removed from the TLBs of other PEs in the system.

In the event of a PE setting the stage 2 S2AP[1] bit to 1, it is not required that all associated entries are removed from the TLBs of other PEs in the system.

For the stage 2 translation tables, it is CONSTRAINED UNPREDICTABLE whether the stage 2 S2AP[1] entry is updated in response to a stage 1 translation table walk where the stage 1 translation system is configured to perform hardware updates to the Access flag or stage 1 AP[2] bit, but the values of the Access flag and AP[2] bit are such that a hardware update to the stage 1 translation table entry being accessed is not required.

In the event of a PE encountering a situation for a data write for which the DBM bit is 1 and the stage 1 AP[2] bit is 1 in a TLB, it is required that the hardware checks that the cached copy is not stale with regards to the translation table entry in memory and performs the atomic read-modify-write update with respect to table entry in memory.

In the event of a PE encountering a situation for a data write for which the DBM bit is 1 and stage 2 S2AP[1] bit is 0 in a TLB, it is required that the hardware checks that the cached copy is not stale with regards to the translation table entry in memory and performs the atomic read-modify-write update with respect to table entry in memory.

For a CAS or CASP instruction to a memory location for which the DBM bit is 1, and the stage 1 AP[2] bit is 1, if the compare fails, and the location is not updated, it is CONSTRAINED UNPREDICTABLE whether the AP[2] bit in the translation table is updated.

For a CAS or CASP instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[1] bit is 0, if the compare fails, and the location is not updated, it is CONSTRAINED UNPREDICTABLE whether the S2AP[1] bit in the translation table is updated.
For an atomic instruction to a memory location for which the DBM bit is 1, and the stage 2 S2AP[0:1] is 00, if the instruction generates a stage 2 Permission fault as a result of not having read permission, it is CONSTRAINED UNPREDICTABLE whether the S2AP[1] bit in the translation table is updated.

**D4.4.10 Ordering of hardware updates to the translation tables**

A hardware update to the translation table that is caused by a load or a store, including an atomic instruction, is guaranteed to be observed, to the extent required by the shareability attributes:

- Before a load or store, including an atomic instruction, to an arbitrary address, other than the address of the translation table entry, that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load or store.

- Before a load to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load.

- Before a store or atomic access to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry.

- Before a cache maintenance instruction to an arbitrary address appearing in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table entry and the subsequent cache maintenance instruction.

An update to the translation table that is caused by a load is not ordered with respect to the load itself.

An update to the translation table that is caused by a store or an atomic access is observed by all observers, to the extent required by the shareability attributes, before the store itself in the case that the store is to the same location as the translation table update.

An update to the translation table that is caused by a store or an atomic access is not ordered with respect to the store itself in the case that the store is not the same location as the translation table update.

**D4.4.11 Restriction on memory types for hardware updates on page tables**

Translation tables can be placed in Normal memory with any cacheability, but the hardware updates to the translation tables require an atomic update of memory. The properties of the atomicity can be met only by functionality outside the PE. Some system implementations might not implement this functionality for all regions of memory. This can apply to:

- Any type of memory in the system that does not support hardware cache coherency.

- Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does not support hardware cache coherency.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the hardware updates of the translation tables will be atomic are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
If the hardware updates of the translation tables are not atomic in regard to other agents that access memory, then performing a hardware update to such a location can have one or more of the following effects:

- The hardware update generates a synchronous External abort, which is presented as an External abort on a translation table walk.
- The instruction generates a SError interrupt.
- The hardware update generates an Unsupported atomic hardware update MMU fault reported using the Fault status code of:
  - \( \text{ESR}_x \text{DFSC} = 110001 \) for Data Aborts.
  - \( \text{ESR}_x \text{IFSC} = 110001 \) for Instruction Aborts.

For the Non-secure EL1&0 translation regime, if atomic hardware update is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.

The priority of this MMU fault for a stage of the translation is immediately before or immediately after the priority of a Permission fault generated by the same stage of translation as the stage of this MMU fault, as determined by an IMPLEMENTATION DEFINED choice.

- The hardware updates are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a SError interrupt.

**D4.4.12 Use of the Contiguous bit with hardware updates of the translation table entries**

Hardware updates of the Access flag, and the AP[2] or S2AP[1] bit, only apply to a single translation table entry. An update to one of these bits in a translation table entry that also has the Contiguous bit set to 1 can give rise to translation table entries that have different Access flag, or different AP[2] or S2AP[1] bits, within the members of a group of contiguous translation table entries.

This is acceptable under the architecture when using hardware updates of the translation table entries. In addition, an access or a write to a location translated by an entry that has the Contiguous bit set might not result in a hardware update of the Access flag or the AP[2] or S2AP[1] bit, if at least one entry in the set of contiguous translation table entries has the Access flag set to 1, or the AP[2] or S2AP[1] bit indicating that the entry is dirty.

---

**Note**

- The provision of the Contiguous bit permits, but does not require, the hardware to hold a single entry in a TLB for the set of translation table entries in the group, and to have updated only one or more of the Access flags and the AP[2] bit or S2AP[1] bit for the single translation table entry that gave rise to the TLB entry.
- A consequence of this is that software must combine the Access flag values, and AP[2] or S2AP[1] values, across all translation table entries in a contiguous group to determine whether any of the entries have been accessed or written to.

For more information on the Contiguous bit, see *The Contiguous bit on page D4-2178.*
D4.5 Memory region attributes

The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent. This section also describes some additional translation table fields, that this manual groups with the memory region attributes.

In the EL1&0 translation regime, each enabled stage of address translation assigns memory region attributes, as described in this section. When both stages of translation are enabled, Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-2179 describes how the assignments from the two stages are combined.

--- Note ---

In a virtualization implementation, a hypervisor, executing at EL2, might usefully:
- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

---

The following sections describe these attributes:
- The stage 1 memory region attributes.
- The stage 2 memory region attributes, EL1&0 translation regime on page D4-2176.
- Other fields in the VMSA v8-64 translation table format descriptors on page D4-2178.
- Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-2179.

--- Note ---

- This section describes the memory region attributes for each of the translation regimes, and for each stage of translation in the Non-secure EL1&0 translation regime.
- A translation applies to memory accesses from either:
  - Only a single Exception level, for example the EL3 translation regime.
  - EL0 and one higher Exception level, for example the EL1&0 translation regime.
- In general, attribute assignment is simpler in a regime that applies to only a single Exception level, and in these regimes behavior is consistent with fields in the translation tables being treated as follows:
  - AP[1] is RES1, meaning the PE ignores the value of the bit and behaves as if it is 1.
  - APTable[0] is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
  - The PXN field is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
  - The PXNTable bit is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.

D4.5.1 The stage 1 memory region attributes

The description of the memory region attributes in a translation descriptor divides into:

Memory type and Cacheability

These are described indirectly, by registers referenced by bits in the table descriptor. This is described as remapping the memory type and attribute description. Stage 1 memory region type and Cacheability attributes on page D4-2175 describes this encoding.

Shareability

The SH[1:0] field in the translation table descriptor encodes shareability information. Stage 1 Shareability attribute, for Normal memory on page D4-2175 describes this encoding.
Stage 1 memory region type and Cacheability attributes

In the VMSAv8-64 translation table format, the AttrIndx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the MAIR_ELx that specifies the attributes for the corresponding memory region. The required field is Attr\textsubscript{n}, where \( n = \text{AttrIndx}[2:0] \). For more information about AttrIndx[2:0] see Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D4-2150.

--- Note ---
Each MAIR_ELx is a 64-bit register that is architecturally mapped to a pair of AArch32 registers. See the MAIR_ELx register descriptions for more information.

Each MAIR_ELx.Attr\textsubscript{n} field defines, for the corresponding memory region:

- The memory type, Device or Normal.
- For Device memory, the Device memory type, one of:
  - Device-nGnRnE.
  - Device-nGnRE.
  - Device-nGRE.
  - Device-GRE.
- For Normal memory:
  - The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back.
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is Allocate or No Allocate, and the Transient allocation hints, if supported.

For more information about the memory type and attributes, see Memory types and attributes on page B2-114 and Cacheability, cache allocation hints, and cache transient hints on page D3-2054.

Stage 1 Shareability attribute, for Normal memory

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-36 shows the encoding of this field.

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE\textsuperscript{a}</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

\textsuperscript{a.} See Reserved values in System and memory-mapped registers and translation table entries on page K1-6427 for the permitted CONSTRAINED UNPREDICTABLE behavior.

--- Note ---
The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.
See [Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-2181](#) for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

### D4.5.2 The stage 2 memory region attributes, EL1&0 translation regime

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- **Stage 2 memory region type and Cacheability attributes** describes how the MemAttr[3:0] field defines these attributes.
- The SH[1:0] field in the translation table descriptor encodes shareability information. **Stage 2 Shareability attribute, for Normal memory on page D4-2177** describes this encoding.

The following sections describe how, when both stages of address translation are enabled, the memory region attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- [Combining the stage 1 and stage 2 memory type attributes on page D4-2180](#)
- [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-2181](#)
- [Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-2181](#)

### Stage 2 memory region type and Cacheability attributes

Table D4-37 shows how MemAttr[3:2] gives a top-level definition of the memory type, and of the Outer cacheability of a Normal memory region.

<table>
<thead>
<tr>
<th>MemAttr[3:2]</th>
<th>Memory type</th>
<th>Outer cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device. MemAttr[1:0] encodes the Device memory type.</td>
<td>Not applicable</td>
</tr>
<tr>
<td>01</td>
<td>Normal. MemAttr[1:0] encodes the Inner Cacheability.</td>
<td>Outer Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td></td>
<td>Outer Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td></td>
<td>Outer Write-Back Cacheable</td>
</tr>
</tbody>
</table>

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2] == 0b00, indicating Device memory, Table D4-38 shows the encoding of MemAttr[1:0].

<table>
<thead>
<tr>
<th>MemAttr[1:0]</th>
<th>Meaning when MemAttr[3:2] == 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Region is Device-nGnRnE memory</td>
</tr>
<tr>
<td>01</td>
<td>Region is Device-nGnRE memory</td>
</tr>
<tr>
<td>10</td>
<td>Region is Device-nGRE memory</td>
</tr>
<tr>
<td>11</td>
<td>Region is Device-GRE memory</td>
</tr>
</tbody>
</table>
• When MemAttr[3:2]!=0b00, indicating Normal memory, Table D4-39 shows the encoding of MemAttr[1:0].

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE(^a)</td>
</tr>
<tr>
<td>01</td>
<td>Inner Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Inner Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Write-Back Cacheable</td>
</tr>
</tbody>
</table>

\(^a\) See [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-6427 for the permitted CONSTRAINED UNPREDICTABLE behavior.

---

**Note**

• The stage 2 translation does not assign any allocation hints.

• The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
  — MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

**Stage 2 Shareability attribute, for Normal memory**

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-40 shows the encoding of this field.

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE(^a)</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

\(^a\) See [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-6427 for the permitted CONSTRAINED UNPREDICTABLE behavior.

---

**Note**

• This encoding is the same as the shareability encoding described in [Stage 1 Shareability attribute, for Normal memory](#) on page D4-2175.

• The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.

See [Combining the stage 1 and stage 2 shareability attributes for Normal memory](#) on page D4-2181 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.
Other fields in the VMSAv8-64 translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors:

- The Contiguous bit.
- IGNORED fields on page D4-2179.
- Field reserved for software use on page D4-2179.

The Contiguous bit

When the value of the Contiguous bit is 1, it indicates that the entry is one of a number of adjacent translation table entries that point to a contiguous output address range. The required number of adjacent entries depends on the current translation granule size, as follows:

4KB granule 16 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 16 entries must be aligned in the translation table. If accessing a full-sized 4KB translation table, this means that the top 5 of the 9 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

16KB granule This bit indicates that adjacent translation table entries point to contiguous output address range that has the same permissions and attributes. With the 16KB granule, the number of contiguous entries indicated by setting this bit to 1 depends on the lookup level of the translation table:

- **Level 2 lookup** The bit indicates 32 contiguous entries, giving a 1GB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 6 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.
  The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

- **Level 3 lookup** The bit indicates 128 contiguous entries, giving a 2MB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 4 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.
  The contiguous output address range must be aligned to size of 128 translation table entries at the same translation table level.

64KB granule 32 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 32 entries must be aligned in the translation table. If accessing a full-sized 64KB translation table, this means that the top 8 of the 13 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Setting this bit to 1 means that the TLB can cache a single entry to cover the contiguous translation table entries.

This section defines the requirements for programming the Contiguous bit. Possible errors in programming the translation table registers on page D4-2131 describes the effect of not meeting these requirements.

The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of the Contiguous bit.

TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues.

Use of the Contiguous bit with hardware updates of the translation table entries on page D4-2173 describes the effect of hardware management of the Access flag and dirty state on the Contiguous bit.
Note

When ARMv8.2-LVA is implemented, the level 1 block size for the 64KB granule does not support the Contiguous bit, and that field is RES0.

IGNORED fields

In the VMSAv8-64 translation table descriptors, the following fields are identified as IGNORED, meaning the architecture guarantees that a PE makes no use of these fields:

• In the stage 1 and stage 2 Table descriptors, bits[58:51] and bits[11:2].
• In the stage 1 and stage 2 Block and Page descriptors, bit[63] and bits[58:55].
• In the stage 1 and stage 2 Block and Page descriptors in an implementation that does not include ARMv8.2-TTPBHA, bits[62:59].

Of these fields:

• In the stage 1 and stage 2 block and page descriptors, bits[58:55] are reserved for software use, see Field reserved for software use.
• In the stage 2 block and page descriptors:
  — Bit[63] is reserved for use by a System MMU.
  — In an implementation that does not include ARMv8.2-TTPBHA, bits[62:59] are reserved for use by a System MMU.

Field reserved for software use

The architecture reserves a 4-bit IGNORED field in the Block and Page table descriptors, bits[58:55], for software use. The definition of IGNORED means the architecture guarantees that hardware makes no use of this field.

Note

This means there is no need to invalidate the TLB if these bits are changed.

D4.5.4 Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime

The Non-secure EL1&0 translation regime comprises two stage of translation, each of which can be enabled independently:

• Stage 1 translation is configured and controlled from EL1. When enabled, stage 1 translation can define access permissions independently for access from EL0 and for accesses from EL1.
  Stage 1 MMU faults are taken to EL1.
• When stage 2 translation is enabled, the stage 2 access controls defined at EL2:
  — Affect only the Non-secure stage 1 access permissions settings.
  — Take no account of whether the accesses are at EL1 or EL0.
  — Permit software executing at EL2 to assign a write-only attribute to a memory region.
  Stage 2 MMU faults are taken to EL2.

Note

In an implementation of virtualization, the attributes defined in the stage 2 translation tables mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

• The Guest OS, in the stage 1 translation tables.
• The hypervisor, in the stage 2 translation tables.
The effects of the combination of attributes defined by the Hypervisor are functionally transparent to the Guest OS.

Combining the stage 1 and stage 2 data access permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in *The AP[2:1] data access permissions, for stage 1 translations on page D4-2157.*
- The stage 2 permissions described in *The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-2158.*

The stage 1 and stage 2 permissions are combined as follows:

1. If an access is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an access is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an access is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

Combining the stage 1 and stage 2 instruction execution permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in *Stage 1 instruction access and execution permissions on page D4-2162.*
- The stage 2 permissions described in *Stage 2 instruction execution permissions on page D4-2163.*

The stage 1 and stage 2 permissions are combined as follows:

1. If an instruction fetch is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an instruction fetch is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an instruction fetch is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

Combining the stage 1 and stage 2 memory type attributes

*Table D4-41* shows the rules for combining the stage 1 and stage 2 memory type assignments.

<table>
<thead>
<tr>
<th>Rule</th>
<th>If either stage of translation assigns:</th>
<th>The resultant memory type is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device has precedence over Normal</td>
<td>Any Device memory type</td>
<td>A Device memory type</td>
</tr>
<tr>
<td>non-Gathering has precedence over Gathering</td>
<td>A Device-nGxx memory type</td>
<td>A Device-nGxx memory type</td>
</tr>
<tr>
<td>non-Reordering has precedence over Reordering</td>
<td>A Device-nGnRx memory type</td>
<td>A Device-nGnRx memory type</td>
</tr>
<tr>
<td>No Early write acknowledge has precedence over Early write acknowledge</td>
<td>The Device-nGnRnE memory type</td>
<td>The Device-nGnRnE memory type</td>
</tr>
</tbody>
</table>
Regardless of any shareability attribute obtained as described in Combining the stage 1 and stage 2 shareability attributes for Normal memory:

- Any location for which the resultant memory type is any type of Device memory is always treated as Outer Shareable.
- Any location for which the resultant memory type is Normal Inner Non-cacheable, Outer Non-cacheable is always treated as Outer Shareable.

For information about how the cacheability attribute is obtained from the attributes assigned at each stage of translation see Combining the stage 1 and stage 2 cacheability attributes for Normal memory.

The combining of the memory type attributes from the two stages of translation means a translation table walk for stage 1 translation can be made to a type of Device memory. If this occurs then:

- If the value of HCR_EL2.PTW is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of HCR_EL2.PTW is 1, then the memory access generates a stage 2 Permission fault.

**Combining the stage 1 and stage 2 cacheability attributes for Normal memory**

For a Normal memory region, Table D4-42 shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes.

### Table D4-42 Combining the stage 1 and stage 2 cacheability assignments for Normal memory

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-cacheable</td>
<td>Any</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>Any</td>
<td>Non-cacheable</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>Write-Through Cacheable</td>
<td>Write-Through or Write-Back Cacheable</td>
<td>Write-Through Cacheable</td>
</tr>
<tr>
<td>Write-Through or Write-Back Cacheable</td>
<td>Write-Through Cacheable</td>
<td>Write-Through Cacheable</td>
</tr>
<tr>
<td>Write-Back Cacheable</td>
<td>Write-Back Cacheable</td>
<td>Write-Back Cacheable</td>
</tr>
</tbody>
</table>

**Combining the stage 1 and stage 2 shareability attributes for Normal memory**

A memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation, if either:

- The resultant memory type attribute, described in Combining the stage 1 and stage 2 memory type attributes on page D4-2180, is any type of Device memory.
- The resultant memory type attribute, described in Combining the stage 1 and stage 2 memory type attributes on page D4-2180, is Normal memory, and the resultant cacheability, described in Combining the stage 1 and stage 2 cacheability attributes for Normal memory, is Inner Non-cacheable, Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal, that is not Inner Non-cacheable, Outer Non-cacheable, Table D4-43 on page D4-2182 shows how the stage 1 and stage 2 shareability assignments are combined.
### Table D4-43 Combining the stage 1 and stage 2 Shareability assignments for Normal memory

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>

<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Non-shareable</td>
<td>Non-shareable</td>
</tr>
</tbody>
</table>

*a. Applies only if the Normal memory is not Inner Non-cacheable, Outer Non-cacheable, see text.*
D4.6 Virtualization Host Extensions

ARMv8.1 introduces the Virtualization Host Extensions that provide enhanced support for a Type 2 virtualization solution, where there is a Host OS, which is either more privileged than the hypervisor, or is a peer of the hypervisor. The Virtualization Host Extensions only apply to an implementation that includes EL2 using AArch64.

D4.6.1 State added by the Virtualization Host Extensions

The following state is added as part of the Virtualization Host Extensions:

- A new configuration bit, E2H, is added to HCR_EL2. This only applies to execution in Non-secure state. When SCR_EL3.NS == 0, HCR_EL2.E2H is treated as 0 for all purposes other than reading or writing the value of the register

- New registers added:
  - TTBR1_EL2, which has the same format and contents as the TTBR1_EL1.
  - CONTEXTIDR_EL2, which has the same format and contents as CONTEXTIDR_EL1.

- A new virtual timer is added to EL2 and is accessed using the registers: CNTHV_CTL_EL2, CNTHV_CVAL_EL2, and CNTHV_TVAL_EL2. The registers take the same format as CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 respectively. The virtual offset is treated as 0 for this timer.

D4.6.2 Behavior of HCR_EL2.E2H

When the value of HCR_EL2.E2H is 0:

- There are no changes to the ARMv8 functionality other than the new state described in State added by the Virtualization Host Extensions.

  — Note —

  This means the translation regime controlled by TCR_EL2 is called the EL2 translation regime.

  —

- The contents of TTBR1_EL2 are ignored by hardware, other than reads by an MSR instruction and writes by an MSR instruction.

- The Context ID matching breakpoint is disabled at EL2, and uses the value of CONTEXTIDR_EL1 at EL0 and EL1.

When the value of HCR_EL2.E2H is 1:

- The translation regime controlled by TCR_EL2 is the EL2&0 translation regime, and the behaviors of this translation regime differ from those of the EL2 translation regime.

- The EL2&0 translation regime behaves in the same way as stage 1 of the EL1&0 translation regime, with an upper address range translated by tables pointed to by TTBR1_EL2. The existing TTBR0_EL2 translates the lower address range of the EL2&0 translation regime and is extended to have the same contents and format as the TTBR0_EL1.

- The translation tables used in the EL2&0 translation regime take the same format as the EL1&0 translation regime. EL2 accesses are treated as privileged in this format.

- Context ID matching can occur at EL2. When executing at EL2, a Context ID matching breakpoint uses CONTEXTIDR_EL2.

- VMID and VMID + Context ID matching breakpoints do not match at EL2.

- The virtual offset is treated as 0 when CNTVCT_EL0 is read from EL2.

- The Privileged Access Never mechanism applies to accesses from EL2 to a virtual address which has access permitted in the EL2&0 translation regime.
The following registers are redefined:

- `CNTHCTL_EL2`.
- `CPTR_EL2`.
- `TCR_EL2`.

If `HCR_EL2.{E2H, TGE} == {1, 0}`, then all accesses from EL1 and EL0 are not included in the EL2&0 translation regime.

If `HCR_EL2.{E2H, TGE} == {1, 1}`:

- The EL2&0 translation regime is used when executing at Non-secure EL0 as well as when executing at EL2, where Non-secure EL0 accesses are treated as unprivileged.

Note
Accesses from Non-secure EL1 are not possible under this configuration.

In EL2, the unprivileged instructions `LDTR`, `LDTRB`, `LDTRH`, `LDTRSB`, `LDTRSH`, `LDTRSW`, `STTR`, `STTRB`, and `STTRH` act as if they are executing at Non-secure EL0 for permission and watchpoint checking.

Except for the purpose of reading the value held in the register, some fields in `HCR_EL2` and all fields in `HSTR_EL2` are treated as having a specific value.

`SCTLR_EL2` is redefined to include additional fields from `SCTLR_EL1`, and to apply to execution at Non-secure EL0.

The following timer registers, and their equivalent AArch32 registers, are redefined to access the associated `_EL2` register, rather than accessing the `_EL0` register when in EL0:

- `CNTP_CTL_EL0`.
- `CNTP_CVAL_EL0`.
- `CNTP_TVAL_EL0`.
- `CNTV_CTL_EL0`.
- `CNTV_CVAL_EL0`.
- `CNTV_TVAL_EL0`.

For some information on registers that are redirected, see System and Special-purpose register redirection on page D4-2185.

When executing at Non-secure EL0, a Context ID matching breakpoint uses `CONTEXTIDR_EL2`.

`VMID` and `VMID + Context ID matching breakpoints do not match at Non-secure EL0`.

The `CPACR_EL1` register does not cause any instructions to be trapped to EL1, regardless of the contents of `CPACR_EL1`.

The `CNTKCTL_EL1` register does not cause any instructions to be trapped to EL1, and the event stream event caused by the `CNTKCTL_EL1` is disabled, regardless of the contents of `CNTKCTL_EL1`.

The virtual offset is treated as 0 when `CNTVCT_EL0` is read from EL0 or EL2.

The TLB maintenance and address translation instructions that apply to the EL1&0 translation regime are redefined to apply to the EL2&0 translation regime. See A64 system instructions for address translation on page C5-432 and A64 System instructions for TLB maintenance on page C5-459.

When executing at EL2 or Non-secure EL0, any physical interrupt that is configured to be taken at EL2 is subject to the Process state interrupt mask. If the mask bit is set, then the corresponding interrupt will not be taken. If the mask bit is not set, then the corresponding interrupt will be taken. See Asynchronous exception masking on page D1-1905.

When an exception is taken from EL0 to EL2, the value of the `HCR_EL2.RW` bit is not considered when determining the exception vector offset to use. Table D1-7 on page D1-1876 lists the vector offsets used when an exception is taken from EL0.
D4.6.3 System and Special-purpose register redirection

When ARMv8.1-VHE is implemented, and HCR_EL2.E2H is set to 1, when executing at EL2, some EL1 System register access instructions are redefined to access the equivalent EL2 register.

--- Note ---

Generally, the value of HCR_EL2.E2H does not affect register access behavior when executing in Secure state or at Non-secure EL1, or at Non-secure EL0 when the value of HCR_EL2.TGE is 0. However, the register descriptions in Chapter D10 AArch64 System Register Descriptions fully describe how ARMv8.1-VHE can affect register access behavior.

Table D4-44 shows the System register access instruction encodings that are redirected to the equivalent EL2 register when the named mnemonic is used.

<table>

#### D4.6.4 System and Special-purpose register aliasing

New register encodings, and aliases, are provided so that software executing at EL2 can access the EL1 registers for which accesses from EL2 are redirected as described in System and Special-purpose register redirection on page D4-2185. These aliases can also be used at EL3, but are UNDEFINED at EL1 and EL0.

Table D4-46 shows the System register access instruction encodings that are aliased.

D4.7 Nested virtualization

ARMv8.3-NV provides support for nested virtualization. This allows a Host hypervisor executing at EL2 to run a Guest hypervisor at Non-secure EL1, regardless of the value of HCR_EL2.E2H. Nested virtualization is supported only in AArch64 state.

Note
- When running a Guest hypervisor with HCR_EL2.E2H == 0, the Host hypervisor must set HCR_EL2.TVM and CPTR_EL2.TCPAC to trap any Guest hypervisor accesses to the Non-secure EL1 System registers that would be accesses from any Guest OS running under the Guest hypervisor
- ARMv8.3-NV does not introduce any changes to either debug or to the Performance Monitors. ARM assumes that the Host hypervisor will trap accesses to the Breakpoint and Performance Monitors registers to EL2, so that it can process any accesses to these registers made by a Guest hypervisor or by a Guest OS running under the Guest hypervisor.

ARMv8.3-NV adds the fields HCR_EL2.{NV, NV1}, see:
- Effect of HCR_EL2.{NV, NV1} on page D4-2190.

D4.7.1 Effect of HCR_EL2.{NV, NV1}

The following subsections describe the effect of HCR_EL2.{NV, NV1}:
- Behavior when HCR_EL2.NV==1.
- Additional behavior when HCR_EL2.NV==1 and HCR_EL2.NV1==0 on page D4-2189.
- Additional behaviors when HCR_EL2.NV==1 and HCR_EL2.NV1==1 on page D4-2189.
- Behavior when HCR_EL2.NV==0 and HCR_EL2.NV1==1 on page D4-2189.

HCR_EL2.{NV, NV1} are both permitted to be cached in a TLB.

Behavior when HCR_EL2.NV==1

The following behaviors apply when the value of HCR_EL2.NV is 1, regardless of the value of HCR_EL2.NV1. At Non-secure EL1:
- Reads or writes to any allocated and implemented System register or Special-purpose register named *_EL2, *_EL02, or *_EL12 in the MRS or MSR instruction, other than SP_EL2, are trapped to EL2 rather than being UNDEFINED. In this case, ESR_EL2 uses the EC code of 0x18.

Only accesses that are permitted at EL2 are trapped. This means that, for example, if the register is a read-only register at EL2, then an MSR from Non-secure EL1 to the register is not trapped by this mechanism. Instead the register access remains UNDEFINED.

Note
- The priority of this trapping relative to other configurable traps follows the standard hierarchy of exceptions, see Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895.

- Reads or writes to SPSR_irq, SPSR_abt, SPSR_und, or SPSR_fiq using MSR and MSR instructions are trapped to EL2 rather than being UNDEFINED. In this case the exception is reported in ESR_EL2 using the EC code 0x18.
- Reads or writes to SP_EL1 using the dedicated MSR and MSR instruction for accessing that register are trapped to EL2 rather than being UNDEFINED. In this case the exception is reported in ESR_EL2 using the EC code 0x18.
- Execution of the EL2 translation regime Address translation instructions and TLB maintenance instructions are trapped to EL2 rather than being UNDEFINED. In this case the exception is reported in ESR_EL2 using the EC code 0x18.
• Execution of the EL1 translation regime Address translation instructions and TLB maintenance instructions that are only accessible from EL2 and above are trapped to EL2 rather than being UNDEFINED. In this case the exception is reported in ESR_EL2 using the EC code 0x18.

• The ERETA, ERETB, and ERET instructions are trapped to EL2. In this case the exception is reported in ESR_EL2 using the EC code 0x1A.

——— Note ————
The ERETA and ERETB instructions are only available when ARMv8.3-PAuth is implemented.

• A read of CurrentEL returns the value 0x2 in bits[3:2].

• If EL3 is not implemented and HCR_EL2.TSC == 1, an $c instruction executed at Non-secure EL1 is trapped to EL2 rather than being UNDEFINED, and HCR_EL2.TSC is not RES0. In this case the exception is reported in ESR_EL2 using the EC code 0x17.

Additional behavior when HCR_EL2.NV==1 and HCR_EL2.NV1==0
At Non-secure EL1, all the behaviors described in Behavior when HCR_EL2.NV==1 on page D4-2188 apply.
In addition, when HCR_EL2.{NV, NV1}=={1, 0}, any exception taken from Non-secure EL1 to Non-secure EL1 causes SPSR_EL1.M[3:2] to be set to 0b10 rather than 0b01.

Additional behaviors when HCR_EL2.NV ==1 and HCR_EL2.NV1 == 1
At Non-secure EL1, all the behaviors described in Behavior when HCR_EL2.NV==1 on page D4-2188 apply.
In addition, when HCR_EL2.{NV, NV1}=={1, 1}:

• Accesses to VBAR_EL1, ELR_EL1, and SPSR_EL1 from Non-secure EL1 are trapped to EL2. In this case the exception is reported in ESR_EL2 using the EC code 0x18.

• In the Non-secure EL1 translation table Block and Page descriptors:
  — Bit[54] holds PXN, not UXN.
  — Bit[53] is RES0.
  — Bit[6] is treated as 0 regardless of the actual value.

• If Hierarchical permissions are enabled, then in the Non-secure EL1 translation table Table descriptor:
  — Bit[61] is treated as 0 regardless of the actual value.
  — Bit[60] holds PXNTable, not UXNTable.
  — Bit[59] is RES0.

• When in Non-secure EL1, PSTATE.PAN is treated as 0 for all purposes except reading the value of the bit.

• When executed at Non-secure EL1, the LDTR* behave as the corresponding LDR* instructions, and the STTR* instructions behave as the equivalent STR* instructions.

Behavior when HCR_EL2.NV ==0 and HCR_EL2.NV1 ==1
When HCR_EL2.{NV, NV1}=={0, 1}, the behavior is a CONSTRAINED UNPREDICTABLE choice of:

• Behaving as if HCR_EL2.NV==1 and HCR_EL2.NV1==1 for all purposes other than reading back the value of the HCR_EL2.NV bit.

• Behaving as if HCR_EL2.NV==0 and HCR_EL2.NV1==0 for all purposes other than reading back the value of the HCR_EL2.NV1 bit.

• Behaving as defined for HCR_EL2.NV==0, with HCR_EL2.NV1==1 having the effect of causing accesses to VBAR_EL1, ELR_EL1, and SPSR_EL1 from Non-secure EL1 to be trapped to EL2.
D4.7.2 Effect of HCR_EL2.AT

When ARMv8.3-NV is implemented, if HCR_EL2.AT is 1, then Non-secure EL1 accesses to AT S1E0R, AT S1E0W, AT S1E1R, AT S1E1W, AT S1E1RP, and AT S1E1WP, are trapped to EL2. In this case the exception is reported in ESR_EL2 using the EC code 0x18.
D4.8 VMSAv8-64 memory aborts

In a VMSAv8-64 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

**Debug exception**

An exception caused by the debug configuration, see Chapter D2 AArch64 Self-hosted Debug.

**Alignment fault**

An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information, see Alignment support on page B2-109.

**MMU fault**

An MMU fault is a fault generated by the fault checking sequence for the current translation regime. See Types of MMU faults on page D4-2192.

**External abort**

Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called aborts. Chapter D2 AArch64 Self-hosted Debug and on page H3-5735 describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

An access that causes an abort is said to be aborted, and uses the Fault Address Registers (FARs) and Exception Syndrome Registers (ESRs) to record context information.

In AArch64 state MMU faults are synchronous exceptions that are reported as either:

- Data Aborts.
- Instruction Aborts

_____ Note _____

Instruction Aborts report any synchronous memory abort on an instruction fetch.

The Exception level that an MMU fault is taken to depends on the translation regime and stage that generated the fault. The fault context saved in the appropriate ESR_ELx, where ELx is the Exception level that the fault is taken to, is dependent on whether:

- The MMU fault is reported as an Instruction or as a Data Abort.
- The exception is taken from the same or a lower Exception level.

For more information, see Synchronous exception types, routing and priorities on page D1-1894.

External aborts can be reported synchronously or asynchronously. Asynchronous External aborts are reported using the SError interrupt. For more information, see External aborts on page D3-2074.

Software stepping, which is a debug feature, and a PC alignment fault exception are the only exceptions that are higher priority than an Instruction Abort. Only watchpoints are at a lower priority than Data Aborts in the exception priority hierarchy. For more information, see Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895.

The following sections describe the abort mechanisms:

- Types of MMU faults on page D4-2192.
- The MMU fault-checking sequence on page D4-2194.
- AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-2198.
- Pseudocode description of the MMU faults on page D4-2200.
D4.8.1 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in *The MMU fault-checking sequence on page D4-2194*. The following list includes all the types of exceptions that can occur:

- Alignment fault on a data access, see *Alignment support on page B2-109*.
- Permission fault.
- Translation fault.
- Address size fault.
- Synchronous External abort on a translation table walk.
- Access flag fault.
- TLB conflict abort.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as Device.

The following subsections describe the MMU faults that are not described elsewhere this Manual.

**Permission fault**

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See *About access permissions on page D4-2155* for information about conditions that cause a Permission fault.

A TLB might hold a translation table entry that causes a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access.

This maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache maintenance instructions cannot generate Permission faults, except that:

- A stage 1 translation table walk performed as part of a cache maintenance instruction can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk*.
- When the value of SCTLR_EL1.UCI is 1, enabling EL0 execution of the DC_CVAU, DC_CVAC, DC_CVAP, DC_CIVAC, and IC_IVAU instructions:
  - Executing a DC_CVAU, DC_CVAC, DC_CVAP, or DC_CIVAC instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault, subject to the constraints described in this section.
  - It is IMPLEMENTATION DEFINED whether executing an IC_IVAU instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault.
- A DC_IVAC instruction requires write permission to the address it invalidates, otherwise it generates a Permission fault, subject to the constraints described in this section.

**Note**

- Execution of the DCIVAC instruction in AArch32 state does not have this write permission requirement.
- When Non-secure EL1&0 stage 2 address translation is enabled, a DC_IVAC instruction executed in Non-secure state performs a cache clean and invalidate, meaning it performs the same invalidation as a DC_CIVAC instruction, as described in *Effects of virtualization and Security state on the cache maintenance instructions on page D3-2067*. 

---

D4-2192 Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved. ARM DDI 0487C.a Non-Confidential ID121917
In all cases where the execution of a cache maintenance instruction might generate a Permission fault:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA to the Point of Coherency instruction can generate a Permission fault.

- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault.

The Data Cache Zero instruction, \texttt{DC ZVA}, operates as set of stores to each byte within the block being accessed, and therefore it generates a Permission fault if the translation system does not permit writes to these locations.

\textbf{Translation fault}

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information, see VMSAv8-64 translation table format descriptors on page D4-2143.

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a TTBR\_ELx, or the TTBR\_ELx range that it maps onto is disabled. In these cases, the fault is reported as a level 0 Translation fault on the translation stage at which the mapping to a region described by a TTBR\_ELx failed.

A data or unified cache maintenance by VA instruction can generate a Translation fault, except that:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA instruction can generate a Translation fault.

- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

\textbf{Address size fault}

An Address size fault can be generated at any level of lookup.

An Address size fault is generated if one of the following has nonzero address bits above the output address size, for the current stage of translation:

- The TTBR\_ELx used for the translation.

- A translation table entry.

- The output address of the translation.

For an Address size fault generated because the TTBR\_ELx used for the translation has nonzero address bits above the output address size, the reported fault code indicates a fault at level 0. Otherwise, the reported fault code indicates the lookup level at which the fault occurred.

A data or unified cache maintenance by VA instruction can generate an Address size fault, except that:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA instruction can generate an Address size fault.

- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate an Address size fault.
The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

For more information on Address size faults, see *Output address size* on page D4-2098.

**External abort on a translation table walk**

An External abort on a translation table walk can be either synchronous or asynchronous. An External abort on a translation table walk is reported:

- If the external abort is synchronous, using:
  - A synchronous Instruction Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the External abort is asynchronous, using the SError interrupt exception.

**Behavior of External aborts on a translation table walk caused by address translation instructions**

The address translation instructions summarized in *Address translation instructions on page C5-334* require translation table walks. An External abort can occur in the translation table walk. This is reported as follows:

- If the External abort is synchronous, using a synchronous Data Abort exception.
- If the External abort is asynchronous, using the SError interrupt exception.

For more information, see *Synchronous faults generated by address translation instructions on page D4-2140.*

**Access flag fault**

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if a translation table descriptor with the Access flag bit set to 0 is used.

For more information about the Access flag bit, see *VMSAv8-64 translation table format descriptors on page D4-2143.*

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to execute any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance by VA instructions can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see *The Access flag on page D4-2165.*

**D4.8.2 The MMU fault-checking sequence**

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- If an instruction fetch faults, it generates an Instruction Abort.
- If a data memory access faults, it generates a Data Abort.

MMU fault checking is performed for each stage of address translation.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see *About address translation and supported input address ranges on page D4-2094.*

---

**Note**

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in *TLB conflict aborts on page D4-2206.*

*Types of MMU faults on page D4-2192* describes the faults that an MMU fault-checking sequence can report.
Figure D4-18 shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, if the translation is stage 1 of the Non-secure EL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

Figure D4-18 Fetching the descriptor in a VMSAv8-64 translation table walk

Figure D4-19 on page D4-2196 shows the full VMSA fault checking sequence, including the alignment check on the initial access.
Figure D4-19 VMSAv8-64 fault checking sequence

1 Is the access subject to an alignment check?
2 Does the address map to a TTBR?
3 Not permitted at the lowest lookup level
4 Fault any unaligned access to Device memory
Stage 2 fault on a stage 1 translation table walk

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous External abort on the memory access.

If SCR_EL3.EA is set to 1, a synchronous External abort is taken to EL3. Otherwise, these faults are reported as stage 2 memory aborts. ESR_EL2.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-1876.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device attribute assigned on the stage 2 translation of the address accessed. When the HCR_EL2.PTW bit is set to 1, such an access generates a stage 2 Permission fault.

--- Note ---
On most systems, such a mapping to Device memory on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

---
A TLB might hold entries that depend on the effect of HCR_EL2.PTW. Therefore, if HCR_EL2.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in Non-secure EL1 or Non-secure EL0 state. For more information, see Changing HCR_EL2.PTW on page D4-2220.

A cache maintenance instruction executed at Non-secure EL1 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA instruction can generate a Permission fault in this way.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault in this way.

--- Note ---
This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

---

The level associated with MMU faults

For MMU faults, Table D4-48 shows how the LL bits in the ESR_ELx.STATUS fields encode the lookup level associated with the fault.

<table>
<thead>
<tr>
<th>LL bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Level 0 of translation or translation table base register.</td>
</tr>
<tr>
<td>01</td>
<td>Level 1.</td>
</tr>
<tr>
<td>10</td>
<td>Level 2.</td>
</tr>
<tr>
<td>11</td>
<td>Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved.</td>
</tr>
</tbody>
</table>
The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see Synchronous External aborts from address translation caching structures on page D4-2200

D4.8.3 AArch64 state prioritization of synchronous aborts from a single stage of address translation

Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1895 describes the prioritization of exceptions taken to an Exception level that is using AArch64. This section gives additional information about the prioritization of MMU faults from VMSAv8-64 translation regimes.

Note

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-64 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4941.

For a single stage of translation in a VMSAv8-64 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

- For memory accesses that undergo two stages of translation, the italic entries show where the faults from the stage 2 translation can occur. A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults:
  - For synchronous External aborts from translation table walks, see also Synchronous External aborts from address translation caching structures on page D4-2200.

The prioritization between the stage 2 permission failure on the stage 1 translation table walk and the stage 1 abort generated by the stage 1 translation table entry is IMPLEMENTATION DEFINED if all the following are true:

- Stage 1 hardware updating of either access or dirty information is enabled.
- A stage 1 translation table entry results in the stage 1 translation table entry having the access or dirty bit updated.
- The stage 1 translation table entry has stage 2 read permission but not stage 2 write permission.
- The stage 1 translation entry generates an abort (which might be one of an address size fault, an alignment fault caused by memory type or a permission fault).

The priority order, from highest priority to lowest priority, is:

1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring a TTBR_ELx that is disabled. This includes VTCR_EL2.SL0 being inconsistent with VTCR_EL2.T0SZ or programmed to a reserved value.
3. Address size fault on a TTBR_ELx caused by either:
   - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
   - The PA being out of the range implemented.
4. **Second stage abort on a level 0 memory access of a a stage 1 table walk.** When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

5. Synchronous parity or ECC error on a level 0 lookup of a translation table walk.

6. Synchronous External abort on a level 0 lookup level of a translation table walk.

7. Translation fault on a level 0 translation table entry.

8. Address size fault a level 0 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

9. **Second stage abort on a level 1 memory access of a a stage 1 table walk.** When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

10. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.

11. Synchronous External abort on a level 1 lookup level of a translation table walk.

12. Translation fault on a level 1 translation table entry.

13. Address size fault on a level 1 lookup translation table entry caused by either:
    - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
    - The output address being out of the range implemented.

14. **Second stage abort on a level 2 memory access of a a stage 1 table walk.** When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

15. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.

16. Synchronous External abort on a level 2 lookup level of a translation table walk.

17. Translation fault on a level 2 translation table entry.

18. Address size fault on a level 2 lookup translation table entry caused by either:
    - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
    - The output address being out of the range implemented.

19. **Second stage abort on a level 3 memory access of a a stage 1 table walk.** When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

20. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.

21. Synchronous External abort on a level 3 lookup level of a translation table walk.

22. Translation fault on a level 3 translation table entry.

23. Address size fault on a level 3 lookup translation table entry caused by either:
    - The check on TCR_EL1.IPS, TCR_EL2.PS, TCR_EL3.PS, or VTCR_EL2.PS.
    - The output address being out of the range implemented.

25. Alignment fault caused by the memory type.

26. Permission fault.

27. **A fault from the stage 2 translation of the memory access.** When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.
28. Synchronous parity or ECC error on the memory access.
29. Synchronous External abort on the memory access.

--- Note ----------------------------------

- The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

- The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

---

### Synchronous External aborts from address translation caching structures

A caching structure used for caching translation table walks might support:

- An arbitrary number of levels of translation table lookup.
- One or more stages of translation, that might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous External aborts arising from the caching structure, including parity or ECC errors, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

- If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.
- If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
  - The lowest-numbered level that could have given rise to the error.
  - Level 0 if it the PE cannot determine any information about the level.

### D4.8.4 Pseudocode description of the MMU faults

The following functions generate fault records that describe MMU faults:

- `AArch64.AccessFlagFault()`.
- `AArch64.AddressSizeFault()`.
- `AArch64.PermissionFault()`.
- `AArch64.TranslationFault()`.

*Abort exceptions on page D3-2079* describes how fault records are used.
D4.9 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and the VMSA provides TLB maintenance instructions for the management of TLB contents.

Note

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

The following sections describe the architectural requirements for Translation Lookaside Buffers (TLBs) and their maintenance:

- Use of ASIDs and VMIDs to reduce TLB maintenance requirements.
- About ARMv8 Translation Lookaside Buffers (TLBs) on page D4-2203.
- TLB maintenance requirements and the TLB maintenance instructions on page D4-2207.

In these descriptions, TLB entries for a translation regime for a particular Exception level are out of context when executing at a higher Exception level.

D4.9.1 Use of ASIDs and VMIDs to reduce TLB maintenance requirements

To reduce the need for TLB maintenance on context switches, the lookups from some translation regimes can be associated with an ASID, or with an ASID and a VMID, as follows:

**ASID**

For stage 1 of a translation regime that can support two VA ranges the VMSA can distinguish between Global pages and Process-specific pages. The Address Space Identifier (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

For these stage 1 translations, each of TTBR0_ELx and TTBR1_ELx has a valid ASID field, and TCR_ELx.A1 determines which of these holds the current ASID.

Note

The selected ASID applies regardless of which set of translation tables are used. For example, when the value of TCR_ELx.A1 is 0, any translation table lookup using this stage of translation is associated with the ASID from TTBR0_ELx.ASID, regardless of whether the translation lookup uses TTBR0_ELx or TTBR1_ELx.

See also ASID size on page D4-2202 and Global and process-specific translation table entries on page D4-2204.

For a symmetric multiprocessor cluster where a single operating system is running on the set of processing elements, the ARM architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all processing elements in the system.

**VMID**

For the Non-secure EL1&0 translation regime, the virtual machine identifier (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another if the virtual machines have different VMIDs.

VTTBR_EL2.VMID holds the current VMID.
Common not private translations

In an implementation that includes ARMv8.2-TTCNP, multiple PEs in the same Inner Shareable domain can use the same translation table entries for a given stage of translation in a particular translation regime. This sharing is enabled by the TTBR_ELx.CnP field for the stage of address translation.

When the value of a TTBR_ELx.CnP field is 1, translation table entries pointed to by that TTBR_ELx are shared with all other PEs in the Inner Shareable domain for which for which the following conditions are met:

- The corresponding TTBR_ELx.CnP field has the value 1.
- That TTBR_ELx relates to the same translation regime.

Note — For TTBR0_EL1 the current Security state determines whether the register relates to the Secure EL1&0 translation regime, or to the Non-secure EL1&0 translation regime.
— For TTBR0_EL2 the value of HCR_EL2.E2H determines whether the register relates to the EL2 translation regime, or to the EL2&0 translation regime.

- If an ASID applies to the stage of translation corresponding to that TTBR_ELx then the current ASID value must be the same for all of the PEs that are sharing entries.
- If a VMID applies to the stage of translation corresponding to that TTBR_ELx then the current VMID value must be the same for all of the PEs that are sharing entries.

Where a TLB combines information from stage 1 and stage 2 translation table entries into a single entry, this entry can be shared between different PEs only if the value of the TTBR_ELx.CnP bit is 1 for both stage 1 and stage 2 of the translation table walk.

The TTBR_ELx.CnP bit can be cached in a TLB.

For a given TTBR_ELx, if the value of TTBR_ELx.CnP is 1 on multiple PEs in the same Inner Shareable domain, and those PEs meet the other conditions for sharing translation table entries as defined in this section, but those TTBR_ELxs do not point to the same translation table entries, then the system is misconfigured, and performing an address translation using that TTBR_ELx:

- Might generate multiple hits in the TLB, and as a result generate an exception that is reported using the TLB conflict fault code, see TLB conflict aborts on page D4-2206.
- Otherwise, has a CONSTRAINED UNPREDICTABLE result, as described in CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6414.

ASID size

In VMSA8-64, the ASID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and ID_AA64MMFR0_EL1.ASIDBits identifies the supported size.

When an implementation supports a 16-bit ASID, TCR_ELx.AS selects whether the top 8 bits of the ASID are used. When the value of TCR_ELx.AS is 0, ASID[15:8]:

- Are ignored by hardware for every purpose other than direct reads of TTBR0_ELx.ASID and TTBR1_ELx.ASID.
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

Note — VMSA8-32 uses an 8-bit ASID. For backwards compatibility, when executing using translations controlled from an Exception level that is using AArch32, the ASID size remains at 8 bits. If the implementation supports 16-bit ASIDs, the 8-bit ASID used is zero-extended to 16 bits.
D4.9 Translation Lookaside Buffers (TLBs)

[Header: VMID size]

From ARMv8.1, the VMID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and ID_AA64MMFR1_EL1.VMIDBits identifies the supported size.

When ARMv8.1-VMID16 is implemented, VTTBR_EL2[63:48] contains the 16-bit VMID.

When an implementation supports a 16-bit VMID, VTCR_EL2.VS selects whether the top 8 bits of the VMID are used.

When the value of VTCR_EL2.VS is 0, VMID[63:56]:
  - Are ignored by hardware for every purpose other than reads of ID_AA64MMFR1_EL1.
  - Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

ARMv8.1-VMID16 is only supported when EL2 is using AArch64.

D4.9.2 About ARMv8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement for every memory access to perform a translation table walk in memory. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Permission fault might be held in the TLB.
- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in a TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

Note

A TLB can hold a translation table entry that does not itself generate a Translation fault but that points to a subsequent table in the translation table walk. This is referred to as intermediate caching of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- Global and process-specific translation table entries on page D4-2204.
- TLB matching on page D4-2204.
- TLB behavior at reset on page D4-2205.
- TLB lockdown on page D4-2205.
- TLB conflict aborts on page D4-2206.

See also TLB maintenance requirements and the TLB maintenance instructions on page D4-2207.
Global and process-specific translation table entries

In a VMSA implementation, system software can divide the virtual memory map used by a stage of translation that can support two VA ranges into global and non-global regions, indicated by the nG bit in the translation table descriptors:

- \( nG = 0 \) The translation is global, meaning the region is available for all processes.
- \( nG = 1 \) The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by:
  - \( TTBR0\_{ELx}.ASID \), if the value of TCR\(_{ELx}.A1 \) is 0.
  - \( TTBR1\_{ELx}.ASID \), if the value of TCR\(_{ELx}.A1 \) is 1.

As indicated by the nG field definitions, each non-global region has an associated ASID. These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

Note

- The selected ASID applies to the translation of any address for which the value of the nG bit is 1, regardless of whether the address is translated based on TTBR0\(_{ELx}\) or on TTBR1\(_{ELx}\).
- In an implementation that does not include ARMv8.1-VHE, the only stage of translation that can support two VA ranges is stage 1 of the EL1&0 translation regime. In an implementation that includes ARMv8.1-VHE stage 1 of the EL2&0 translation regime also can support two VA ranges.

ASIDs are supported only when stage 1 translations can support two VA ranges. Stage 2 translations, and stage 1 translations that can support only a single VA range do not support ASIDs, and all descriptors in these regimes are treated as global.

In a translation regime that supports global and non-global translations, translation table entries from lookup levels other than the final level of lookup are treated as being non-global, regardless of the value of the nG bit.

When a PE is using the VMSAv8-64 translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information, see Control of Secure or Non-secure memory access on page D4-2154.

TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in TLB maintenance requirements and the TLB maintenance instructions on page D4-2207 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in Using break-before-make when updating translation table entries on page D4-2208 is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:

- Might generate an exception that is reported using the TLB conflict fault code, see TLB conflict aborts on page D4-2206.
- Might lead to CONSTRAINED UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. For more information, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6414.
TLB behavior at reset

The ARM architecture does not require a reset to invalidate the TLBs. The architecture recognizes that an implementation might require caches, including TLBs, to maintain their contents over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore, for ARMv8:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- All TLBs are disabled from reset. All stages of address translation are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information, see Controlling address translation stages on page D4-2095.
- An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device. ARM recommends that if an invalidation routine is required for this purpose, the routine is based on the TLB maintenance instructions described in TLB maintenance instructions on page D4-2209.

Similar rules apply to cache behavior, see Behavior of caches at reset on page D3-2057.

TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- VMSAv8-64 does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that a region of the system instruction encoding space is reserved for IMPLEMENTATION DEFINED functions, see Reserved encodings for IMPLEMENTATION DEFINED registers on page D9-2345. An implementation might use some of these encodings to implement TLB lockdown functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

In an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in Non-secure EL1 or Non-secure EL0 state can be routed to either:

- Non-secure EL1, as a Data Abort exception.
- Non-secure EL2, as a Hyp Trap exception.

For more information, see Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1926.
**TLB conflict aborts**

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

--- **Note** ---

An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by the architecture has not been performed.

---

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort:

- On an instruction fetch is reported as an Instruction Abort, see *ISS encoding for an exception from an Instruction Abort* on page D10-2457.

- On a data access is reported as a Data Abort, see *ISS encoding for an exception from a Data Abort* on page D10-2460.

ARMv8 defines the Fault status encoding of 0b110000 for TLB conflict aborts. On a TLB conflict abort, the returned syndrome includes the address that generated the fault. That is, it includes the address that was being looked up in the TLB.

It is IMPLEMENTATION DEFINED whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

--- **Note** ---

A stage 2 abort cannot be generated if stage 2 of the Non-secure EL1&0 translation regime is disabled.

---

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of a TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort is generated, the resulting behavior is CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-6414. The CONSTRAINED UNPREDICTABLE behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Exception level.
D4.10 TLB maintenance requirements and the TLB maintenance instructions

Translation Lookaside Buffers (TLBs) are an implementation mechanism that caches translations or translation table entries. The ARM architecture does not specify the form of any TLB structures, but defines the mechanisms by which TLBs can be maintained. The following sections describe the VMSA TLB maintenance instructions:

- **General TLB maintenance requirements**.
- **TLB maintenance instructions** on page D4-2209.

See also:

- **Maintenance requirements on changing System register values** on page D4-2220.
- **Atomicity of register changes on changing virtual machine** on page D4-2103.

D4.10.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures to ensure that changes to the translation tables are reflected correctly in those TLB caching structures.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault, provided that the entry does not, itself, cause a Translation fault, an Address size fault, or an Access Flag fault. This means that the entries that can be cached include:

- Entries in translation tables that point to subsequent tables to be used in that stage of translation.
- Stage 2 translation table entries used as part of a stage 1 translation table walk
- Stage 2 translation table entries used to translate the output address of the stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are used during a translation table walk and that are distinct from the data caches in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction of the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries, and in particular for a translation regime that involves two stages of translation, it is recognized that such caching structures might contain:

- Entries containing information from stage 1 translation table entries, at any level of the translation table walk.
- Entries containing information from stage 2 translation table entries, at any level of the translation table walk.
- Entries that combine information from stage 1 and stage 2 translation table entries, at any level of the translation table walk.

**Note**

For the purpose of TLB maintenance, the term **TLB entry** denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entries in caching structures that include any stage 1 information that are used to translate the address being invalidated.

**Note**

- Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.

- As stated in **Global and process-specific translation table entries** on page D4-2204, translation table entries from levels of translation other than the final level are treated as being non-global. ARM expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their ASID, regardless of whether the final level is global. This means that TLB invalidations that involve the ASID require the ASID to match such entries to perform the required invalidation.
• Required to apply to stage 2 entries only, then:
  — It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  — It must apply to caching structures that contain information only from stage 2 translation table entries.

• Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures
  that includes information from either a stage 1 translation table entry or a stage 2 translation table entry,
  including any entry that combines information from both stage 1 and stage 2 translation table entries.

Whenever translation tables entries associated with a particular VMID or ASID are changed, the corresponding
entries must be invalidated from the TLB to ensure that these changes are visible to subsequent execution, including
speculative execution, that uses the changed translation table entries.

Some System register field descriptions state that the effect of the field is permitted to be cached in a TLB. This
means that all TLB entries that might be affected by a change of the field must be invalidated whenever that field
is changed, to ensure that the effect of the change of that control field is visible to subsequent execution, including
speculative execution, that uses that control field. This invalidation is required in addition to, and after, the normal
synchronization of the System registers described in Synchronization requirements for AArch64 System registers on
page D10-2349, and applies to any stage of address translation that is implemented for the translation regime, and
VMID and ASID as appropriate, that is affected by that control field. A control field that is permitted to be cached
in a TLB requires this maintenance even when all stages of address translation are disabled.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory,
software must ensure that any cached copies of affected locations are removed from the caches. For more
information see Cache maintenance requirement created by changing translation table attributes on page D4-2223.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or
an Access Flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag
fault to one that does not fault, does not require any TLB invalidation. However, a Context synchronization event
is required to ensure that instruction fetches are affected by a completed change to translation table entries that, before
the change, generated a Translation, Address size, or Access flag fault.

Special considerations apply to translation table updates that change the memory type, cacheability, or output
address of an entry, see Using break-before-make when updating translation table entries.

Using break-before-make when updating translation table entries

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching
possibly breaking coherency, ordering guarantees or uniprocessor semantics, or possibly failing to clear the
Exclusives monitors, the architecture requires the use of a break-before-make sequence when changing translation
table entries whenever multiple threads of execution can use the same translation tables and the change to the
translation table entries involves any of:

• A change of the memory type.

• A change of the cacheability attributes.

• A change of the output address (OA), if the OA of at least one of the old translation table entry and the new
  translation table entry is writable, including if the DBM bit is set and hardware updates to the dirty bits are
  enabled.

• A change to the size of block used by the translation system. This applies both:
  — When changing from a smaller size to a larger size, for example by replacing a table mapping with a
    block mapping in a stage 2 translation table.
  — When changing from a larger size to a smaller size, for example by replacing a block mapping with a
    table mapping in a stage 2 translation table.

• Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.
A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

In ARMv8.1, with the introduction of hardware updates to the translation table entries, the effects of not following the break-before-make rules are extended.

If the break-before-make rules are not followed for changing the translation table entries, the ARMv8.1 architecture permits that the following failures associated with the hardware updates of the translation table entries could occur:

- The Access flag is not set on such a translation table entry despite the fact that the memory location associated with that entry was accessed.
- The AP[2] or S2AP[1] bit is modified by the hardware on such a translation table entry despite the fact that the memory location associated with that entry was not written to.
- The AP[2] or S2AP[1] bit is not modified by the hardware on such a translation table entry despite the fact that the memory location associated with that entry was written to.
- The ordering required between hardware updates to such a translation table entry and stores appearing later in program order is not followed.

### D4.10.2 TLB maintenance instructions

The architecture defines TLB maintenance instructions, that provide the following:

- Invalidate all entries in the TLB.
- Invalidate a single TLB entry by ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.

Each instruction can be specified as applying only to the PE that executes the instruction, or as applying to all PEs in the same Inner Shareable shareability domain as the PE that executes the instruction.

The following subsubsections describe these instructions:

- TLB maintenance instruction syntax on page D4-2210.
- Operation of the TLB maintenance instructions on page D4-2211.
- Scope of the A64 TLB maintenance instructions on page D4-2212.
- Invalidation of TLB entries from stage 2 translations on page D4-2216.
- Broadcast TLB maintenance between AArch32 and AArch64 on page D4-2217.
- Broadcast TLB maintenance with different translation granule sizes on page D4-2218.
- Ordering and completion of TLB maintenance instructions on page D4-2218.
- TLB maintenance in the event of TLB conflict on page D4-2219.
- The interaction of TLB lock down with TLB maintenance instructions on page D4-2219.

TLB maintenance instructions on page C5-335 describes the encoding of the TLB maintenance instructions.
TLB maintenance instruction syntax

The A64 syntax for TLB maintenance instructions is:

```
TLBI <operation>{, <Xt>}
```

Where:

- `<operation>` is one of ALLE1, ALLE2, ALLE3, ALLE1IS, ALLE2IS, ALLE3IS, VMALLE1, VMALLE1IS, VMALLS12E1, VMALLS12E1IS, ASIDE1, ASIDE1IS, VA(L)E1, VA(L)E2, VA(L)E3, VA(L)E1IS, VA(L)E2IS, VA(L)E3IS, VAA(L)E1, VAA(L)E1IS, IPAS2(L)E1, or IPAS2(L)E1IS.
- `<operation>` has a structure of `<type><level>{IS}` where:
  - `<type>` is one of:
    - `ALL` All translations used at `<level>`. For the scope of all instructions see `ALL` on page D4-2212. The `ALL` instructions are valid for all values of `<level>`.
    - `VMALL` All stage 1 translations used at `<level>` with the current VMID, if appropriate. For the scope of the `VMALL` instructions see `VMALL` on page D4-2213. The `VMALL` instructions are valid only when `<level> == E1`.
    - `VMALLS12` All stage 1 and stage 2 translations used at EL1 with the current VMID, if appropriate. For the scope of the `VMALLS12` instructions see `VMALLS12` on page D4-2213. The `VMALLS12` instructions are valid only when `<level> == E1`.
    - `ASID` All translations used at EL1 with the supplied ASID. For the scope of the `ASID` instructions see `ASID` on page D4-2213. The `ASID` instructions are valid only when `<level> == E1`.
    - `VA(L)` Translations used at `<level>` for the specified address and, if appropriate, the specified ASID. For the scope of the `VA` instructions see `VA` on page D4-2214. For the scope of the `VAL` instructions see `VAL` on page D4-2214. The `VA(L)` instructions are valid for all values of `<level>`.
    - `VAA(L)` Translations used at `<level>` for the specified address, for all ASID values, if appropriate. For the scope of the `VAA` instructions see `VAA` on page D4-2214. For the scope of the `VAA` instructions see `VAL` on page D4-2214. The `VAA(L)` instructions are valid only when `<level> == E1`.
    - `IPAS2(L)` Translations used at `<level>` for the specified IPA that are held in stage 2 only caching structures. For the scope of the `IPAS2` instructions see `IPAS2` on page D4-2215. For the scope of the `IPAS2L` instructions see `IPAS2L` on page D4-2215. The `IPAS2(L)` instructions are valid only when `<level> == E1`.
  - `<level>` defines the Exception level of the translation regime that the invalidation applies to. Is one of:
    - `E1` EL1.
    - `E2` EL2.
    - `E3` EL3.
  - An instruction that applies to the translation regime of an Exception level higher than the Exception level at which the instruction is executed is UNDEFINED. TLBI ALLE1(1S), TLBI IPAS2(L)E1(1S) and TLBI VMALLS12E1(1S) are UNDEFINED at EL1.
    - `L` An optional parameter that indicates that the invalidation only applies to caching of entries returned from the final lookup level of the translation table walk.
All TLB maintenance instructions are UNDEFINED at EL0.

IS
When present, it indicates that the function applies to all TLBs in the Inner Shareable shareability domain. When not present, it indicates that the function applies to all TLBs that contain entries that could be used by the PE that executes the TLBI instruction.

--- Note ---
Refilling a TLB entry that has been invalidated for one PE with an entry that is held in a TLB for a different PE such that it appears to software that the invalidation has not occurred, is not consistent with this definition.

<x_t>
Passes one or both of an address and an ASID as an argument, where required. <x_t> is required for the TLB ASID, TLB VA(L), TLB VAA(L), and TLB IPAS2(L) instructions.

If EL2 is not implemented, the TLBI VA{L}E2, TLBI VA{L}E2IS, TLBI ALLE2, and TLBI ALLE2IS instructions are UNDEFINED.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds a VA, an ASID, or both, use the following register argument format:

Bits[63:48] ASID. These bits are RES0 if the instruction does not require an ASID argument.

Bits[47:44] RES0.

Bits[43:0] VA[55:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:

- **4KB granule size**: All bits are valid and used for the invalidation.
- **16KB granule size**: Bits[1:0] RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- **64KB granule size**: Bits[3:0] are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

These bits are RES0 if the instruction does not require a VA argument.

For TLB maintenance instructions that take an address argument, hardware interprets VA[63:56] as each having the same value as VA[55].

If a TLB maintenance instruction targets a translation regime that is using AArch32, meaning the VA is only 32-bit, then software must treat VA[55:32] as RES0, and these bits are ignored when the instruction is executed.

If the implementation supports 16 bits of ASID then the upper 8 bits of the ASID are RES0 when the context being invalidated only uses 8 bits.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds an IPA, use the following register argument format:

Bits[63:36] RES0.

Bits[35:0] IPA[47:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:

- **4KB granule size**: All bits are valid and used for the invalidation.
- **16KB granule size**: Bits[1:0] RES0 and ignored when the instruction is executed, because IPA[13:12] have no effect on the operation of the instruction.
- **64KB granule size**: Bits[3:0] are RES0 and ignored when the instruction is executed, because IPA[15:12] have no effect on the operation of the instruction.

--- Operation of the TLB maintenance instructions ---
Any TLB maintenance instruction can affect any TLB entries that are not locked down.
The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

--- Note ---
Because there is no guarantee that an unlocked TLB entry remains in the cache, architecturally it is not possible to tell whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.

---

If a TLB maintenance instruction specifies a VA, and a data or instruction access to that VA would generate an MMU abort, the TLB maintenance instruction does not generate an abort. VAs for which a TLB maintenance instruction does not generate an abort include VAs that are not in the range of VAs that can be translated.

When EL3 is implemented:

- The TLB maintenance instructions that apply to the EL1&0 translation regime take account of the current Security state, as part of the address translation required for the TLB operation.

- SCR_EL3.NS modifies the effect of the TLB maintenance instructions as follows:
  - For instructions that apply to the EL1&0 translation regime, the SCR_EL3.NS bit identifies whether the maintenance instructions apply to the Secure or Non-secure EL1&0 translation regime.
  - If EL3 is not implemented, then there is only a single EL1&0 translation regime.
  - For instructions that apply to the EL2 translation regime, or to the EL2&0 translation regime, the SCR_EL3.NS bit must be 1 or the instruction is UNDEFINED.
  - For instructions that apply to the EL3 translation regime, the SCR_EL3.NS bit has no effect.

--- Note ---
An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.

- Previous versions of the ARM architecture included TLB maintenance instructions that operated only on instruction TLBs, or only on data TLBs. From the introduction of ARMv7, ARM deprecated any use of these instructions. In ARMv8:
  - AArch64 state does not include any of these instructions.
  - AArch32 state includes some of these instructions, but ARM deprecates their use.

---

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, when a TLB maintenance instruction is executed, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

--- Note ---
The Contiguous bit does not affect the minimum size of entry that must be invalidated from the TLB

---

Scope of the A64 TLB maintenance instructions

The TLB invalidation instruction <type> affects the different possible cached entries in the TLB as follows:

- **ALL**
  The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with the state specified by SCR_EL3.NS.
  For entries from the Non-secure EL1&0 translation regime, ALL applies to entries with any VMID.
  For entries from a translation regime for which an ASID is valid, the invalidation applies to:
  - All entries above the final level of lookup.
  - All entries at the final level of lookup.
D4 The AArch64 Virtual Memory System Architecture

D4.10 TLB maintenance requirements and the TLB maintenance instructions

--- Note ---
This means the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

VMALL
The invalidation applies to all cached copies of the stage 1 translation table entries, from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:
- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies to:
- All entries above the final level of lookup.
- All entries at the final level of lookup.

--- Note ---
This means the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

VMALL is valid for:
- EL1.
- EL2, when HCR_EL2.{E2H, TGE} is {1, 1}.

VMALLS12
The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:
- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies to:
- All entries above the final level of lookup.
- All entries at the final level of lookup.

--- Note ---
This means the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

VMALLS12 is valid for EL1.
If EL2 is not implemented, or if the TLBI VMALLS12 instruction is executed when the value of SCR_EL3.NS is 0, the instruction is not UNDEFINED but it has the same effect as TLBI VMALL. This is because there are no stage 2 translations to invalidate.

ASID
The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:
- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies only if either:
- The entry is from a level of lookup above the final level and matches the specified ASID.
The entry is a non-global entry from the final level of lookup and matches the specified ASID.

ASID is valid for:
- EL1.
- EL2, when HCR_EL2.{E2H, TGE} is {1, 1}.

VA

The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:
- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies only if one of the following applies:
- The entry is from a level of lookup above the final level and matches the specified ASID.
- The entry is a global entry from the final level of lookup.
- The entry is a non-global entry from the final level of lookup that matches the specified ASID.

VAL

The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level, that would be used with all of:
- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies only if either:
- The entry is a global entry from the final level of lookup.
- The entry is a non-global entry from the final level of lookup that matches the specified ASID.

VAA

The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:
- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies to all of:
- All entries above the final level of lookup.
- All entries at the final level of lookup.

Note

This means the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

VAAL

The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:
- The Security state specified by SCR_EL3.NS.
- For the Non-secure EL1&0 translation regime, the current VMID.

For entries from a translation regime for which an ASID is valid that meet the other specified conditions, the invalidation applies to all entries at the final level of lookup.
Note

This means the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

**IPAS2**

The invalidation applies to all cached copies of the stage 2 translation table entries from any level of the translation table walk required to translate the specified IPA, that both:

- Are held in TLB caching structures holding stage 2 only entries.
- Would be used with the current VMID.

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.

When executed with the SCR_EL3.NS == 0, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2 instruction see *Invalidation of TLB entries from stage 2 translations* on page D4-2216.

**IPAS2L**

The invalidation applies to cached copies of the stage 2 translation table entry from the final level of the stage 2 translation table walk required to translate the specified IPA, that both:

- Are held in TLB caching structures holding stage 2 only entries.
- Would be used with the current VMID.

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.

When executed with the SCR_EL3.NS == 0, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2L instruction see *Invalidation of TLB entries from stage 2 translations* on page D4-2216.

The entries that the invalidations apply to are not affected by the state of any other control bits involved in the translation process. Therefore, the following is a non-exhaustive list of control bits that do not affect how a TLB maintenance instruction updates the TLB entries:

**In AArch64 state**

SCTLR_EL1.M, SCTLR_EL1.M, SCTLR_EL3.{M, RW}, HCR_EL2.{VM, RW}, TCR_EL1.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}, TCR_EL2.{TG0, T0SZ}, TCR_EL3.{TG0, T0SZ}, VTCR_EL2.{SL0, T0SZ}, TTBR0_EL1.ASID, TTBR1_EL1.ASID.

**In AArch32 state**

SCTLR.M, HCR.VM, TTBCR.{EAE, PD1, PD0, N, EPD1, T1SZ, EPD0, T0SZ, A1}, HTC.RT0SZ, VTCR.{SL0, T0SZ}, TTBR0.ASID, TTBR1.ASID, CONTEXTIDR.ASID.
--- Note ---

- ARM expects most TLB maintenance performed by an operating system to occur to the last level entries of the stage 1 translation table walks, and the purpose of the address-based TLB invalidation instructions where the invalidation need only apply to caching of entries returned from the last level of translation table walk of stage 1 translation is to avoid unnecessary loss of the intermediate caching of the translation table entries. Similarly, for stage 2 translations ARM expects that most TLB maintenance performed by a hypervisor for a given Guest operation system will affect only the last level entries of the stage 2 translations. Therefore, similar capability is provided for instructions that invalidate single stage 2 entries.

- The architecture permits the invalidation of entries in TLB caching structures at any time, so for each of these instructions the definition is in terms of the minimum set of entries that must be invalidated from TLB caching structures, and an implementation might choose to invalidate more entries. In general, for best performance, ARM recommends not invalidating entries that are not required to be invalidated.

- Dependencies on the VMID for the Non-secure EL1&0 translation regime apply even when the value of HCR_EL2.VM is 0. The VTTBR_EL2.VMID field resets to a value that is architecturally UNKNOWN, and therefore VTTBR_EL2.VMID[7:0] must be set to a known value, that might be zero, as part of the PE initialization sequence, even if stage 2 translation is not in use.

---

**Invalidation of TLB entries from stage 2 translations**

The architectural requirements of the IPAS2 instruction are that:

1. The following code is sufficient to invalidate all cached copies of the stage 2 translation of the IPA held in Xt for the current VMID, with the corresponding requirement for the broadcast versions of the instructions:
   
   TLBI IPAS2E1, Xt
   DSB
   TLBI VMALLE1

2. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the IPA held in Xt used to translate the VA (and the specified ASID when executing TLBI VAE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:
   
   TLBI IPAS2E1, Xt
   DSB
   TLBI VAE1, Xt2 ; or TLBI VAAE1, Xt2

3. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the IPA held in Xt used to translate the IPA produced by the last level of stage 1 translation table lookup for the VA (and ASID when executing TLBI VALE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:
   
   TLBI IPAS2E1, Xt
   DSB
   TLBI VALE1, Xt2 ; or TLBI VAASE1, Xt2

--- Note ---

Depending on the invalidation required, software must use the entire sequence 1, 2, or 3, even when Non-secure EL1&0 stage 1 translation is disabled.

---

Equivalent architectural requirements apply to the IPAS2L instruction, except that the only TLB entries that must be invalidated by an IPAS2L instruction are those that come from the final level of the translation table lookup.
Broadcast TLB maintenance between AArch32 and AArch64

In most cases, a TLB maintenance instruction affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch64 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch32, provided that the address, qualify the scope of the ASID and VMID matching requirements of the original instruction are met, as specified in Scope of the A64 TLB maintenance instructions on page D4-2212.

Note

The requirement to match means that the invalidation only occurs on the PE that is using AArch32 if, for the PE that executed the TLB maintenance instruction at an Exception level that is using AArch64, both of the following apply:

- If VA matching is required, the VA is 0x0000FFFFFF or lower in the memory map.
- If ASID matching is required and the PE is using a 16-bit ASID, then the top 8 bits of the ASID are zero.

Except for the cases identified here, a TLB maintenance instructions affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch32 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch64, provided that the address, ASID, and VMID matching requirements of the original instruction are met, as specified in Scope of the A64 TLB maintenance instructions on page D4-2212. In addition, for the instruction executed in AArch32 state:

- For a TLBIMVAALIS, TLBIMVAALIS, TLBIMVAHIS, TLBIMVAIS, TLBIMVALHIS, or TLBIMVALIS instruction, the VA supplied as an argument is zero-extended.
- For a TLBIIPAS2IS or TLBIIPAS2LIS instruction, the IPA supplied as an argument is zero-extended.
- For a TLBIASIDIS, TLBIMVAIS, or TLBIMVALIS instruction, the ASID supplied as an argument is zero-extended if the PE executing in AArch64 state is using a 16-bit ASID.

The VA from the instruction executed in AArch32 state is zero-extended, and the ASID is zero-extended if the PE executing in AArch64 state is using a 16-bit ASID.

The exceptions to these general rules are as follows:

1. An ARMv7 PE in the same Inner Shareable domain is treated in the same way as an ARMv8 PE for which EL3 is using AArch32, except that if an ARMv8 PE issues a broadcast instruction that is not defined in ARMv7, then that instruction is not required to have an effect on the TLBs of the ARMv7 PE. The instructions that do not exist in ARMv7 include the following TLB maintenance instructions that ARMv8 adds to the T32 and A32 instruction sets:

   - The following instructions that operate on TLB entries for the final level of translation table walk for stage 1 translations:
     TLBIMVALIS, TLBIMVAALIS, TLBIMVAHIS, TLBIMVAIS, TLBIMVALHIS, and TLBIMVALH.
   - The following instructions that operate by IPA on TLB entries for stage 2 translations:
     TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, and TLBIIPAS2L.

2. The number of Exception levels in Secure state depends on whether EL3 is using AArch32 or EL3 is using AArch64. This means that, within the Inner Shareable domain, there might be PEs with different numbers of Exception levels in Secure state. Therefore, the following exceptions are made to the general rules:

   - If a PE with EL3 using AArch32 issues a broadcast AArch32 TLB maintenance instruction affecting Secure entries, and the Inner Shareable domain also contains PEs with EL3 using AArch64, then the architecture does not require that the broadcast AArch32 TLB maintenance instruction has any effect on either:
     - The EL3 translation regime of the PEs with EL3 using AArch64.
     - The Secure EL1&0 translation regime of the PEs with EL3 using AArch64, regardless of whether the Secure EL1&0 translation regime is using AArch64 or AArch32.
• If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting EL3 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32, then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

• If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting Secure EL1 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32 then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

**Note**

While the exceptions to the general rule mean the architecture does not require the specified TLB invalidations, the architecture also does not require that entries in the TLB remain in the TLB at any time, and so it is permissible that such broadcast instructions affect these translation regimes.

**Broadcast TLB maintenance with different translation granule sizes**

In the following cases, a broadcast TLB maintenance instruction is not required to perform any invalidation on the recipient PE:

• The TLB maintenance instruction specifying a VA and affecting the EL2 translation regime, the EL2&0 translation regime, or the EL3 translation regime is broadcast from a PE using one translation granule size for that translation regime to a PE using a different translation granule size for that same translation regime.

• The TLB maintenance instruction specifying a VA and affecting the EL1&0 translation regime is broadcast from a PE using one stage 1 translation granule size for that translation regime for a particular ASID (if applicable), VMID (if applicable), and Security state, to a PE where EL1 for the same ASID (if applicable), VMID (if applicable), and Security state, is using a different stage 1 translation granule size.

• The TLB maintenance instruction specifying a VA and affecting the Non-secure EL1&0 translation regime is broadcast from a PE using one stage 2 translation granule size for a particular ASID (if applicable) and VMID, to a PE where EL1 for the same ASID (if applicable) and VMID is using a different stage 2 translation granule size.

• The TLB maintenance instruction specifying an IPA and affecting the Non-secure EL1&0 translation regime is broadcast from a PE using one stage 2 translation granule size for a particular VMID to a PE where EL1 for the same VMID is using a different stage 2 translation granule size.

**Ordering and completion of TLB maintenance instructions**

For AArch64 execution, a TLB maintenance instruction can be executed in any order relative to:

• Any load or store instruction, unless a **DSB** is executed between the load or store and the TLB maintenance instruction.

**Note**

In the ARM architecture, a translation table walk is considered to be a separate observer, and a store to the translation tables can be observed by that separate observer at any time after the instruction has been executed, but is only guaranteed to be observable after the execution of a **DSB** instruction by the PE that executed the store to the translation tables.

• Another TLB maintenance instruction, unless a **DSB** is executed between the instructions.

• A data or instruction cache maintenance instruction, unless a **DSB** is executed between the instructions.

For AArch64 execution, the completion rules are:

• A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.
After the TLB invalidate instruction is complete, no new memory accesses using the invalidated TLB entries will be architecturally performed by any observer that is affected by the TLB invalidation.

--- Note ---

This requirement does not mean that speculative memory accesses cannot be performed using those entries if it is impossible for software running on any observer to tell that those memory accesses have been performed.

• A TLB maintenance instruction can complete at any time after it is issued, but is only guaranteed to be complete after the execution of a DSB by the PE that executed the TLB maintenance instruction.

• The effects of a completed TLB maintenance instruction are only guaranteed to be visible on the PE that executed the instruction after the execution of a Context synchronization event by the PE that executed the TLB maintenance instruction.

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

**TLB maintenance in the event of TLB conflict**

In the event that multiple entries in the TLB are being used to translate a given address (which implies that an attempt to access the given address might give rise to a TLB Conflict abort), it is IMPLEMENTATION DEFINED as to the form of TLB maintenance operation that the software must perform in order to be guaranteed that all TLB entries associated with the given address and translation regime have been invalidated. In all cases, an ALL or VMALL form of TLB maintenance operation that targets the given translation regime is guaranteed to remove all entries within that regime, even if there are multiple, conflicting TLB entries for any given address within that regime.

**The interaction of TLB lockdown with TLB maintenance instructions**

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

• The effect on a locked TLB entry of a TLB invalidate all operation that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  — The operation has no effect on entries that are locked down.
  — The operation generates an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down.

  Any such exceptions taken from Non-secure EL1 can be trapped to EL2, see *Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations* on page D1-1926.

--- Note ---

These options permit a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

• The effect on a locked TLB entry of a TLB invalidate by VA or invalidate by ASID match operation that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  — The locked entry is invalidated in the TLB.
  — The operation has no effect on any locked entry in the TLB. In the case of an invalidate single entry by VA, this means the PE treats the operation as a NOP.
  — The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down.

The exception syndrome definitions include a fault code for cache and TLB lockdown faults, see *ESR_EL1, Exception Syndrome Register (EL1)* on page D10-2431.
Note

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling the effect of TLB maintenance instructions on entries that can be locked down but are not actually locked down must provide an IMPLEMENTATION DEFINED mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see The interaction of cache lockdown with cache maintenance instructions on page D3-2072.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of any TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

D4.10.3 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB entries associated with a translation regime affected by these control bits must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMI D or ASID, if appropriate depending on the translation regime, that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```assembly
; Change control bits in System registers
ISB ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that maintenance requirement applies to are:
- Any change to the MAIR_EL1, MAIR_EL2, or MAIR_EL3 registers.
- Any change to the AMAIR_EL1, AMAIR_EL2, or AMAIR_EL3 registers.
- Any change to SCTLR_EL1.EE, SCTLR_EL2.EE, or SCTLR_EL3.EE.
- Any change to SCTLR_EL1.WXN, SCTLR_EL2.WXN, or SCTLR_EL3.WXN.
- Any change to any of the SCR_EL3.{RW, SIF} bits.
- Any change to any of the HCR_EL2.{RW, DC, PTW, VM} bits. See also Changing HCR_EL2.PTW.
- Any changes to the registers that control address translation:
  - Any change to any of the TCR_EL1, TCR_EL2, TCR_EL3, or VTCR_EL2 registers.
  - Any change to the TTBR0_EL1, TTBR1_EL1, TTBR1_EL2, TTBR0_EL2, TTBR0_EL3, or VTTBR_EL2 registers.

Changing HCR_EL2.PTW

When the value of the Protected table walk bit, HCR_EL2.PTW, is 1, a stage 1 translation table access in the Non-secure EL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMI D might hold entries that depend on the effect of HCR_EL2.PTW. Therefore, if the value of HCR_EL2.PTW is changed without a change to the VMI D value, all TLB entries associated with the current VMI D must be invalidated before executing software at Non-secure EL1 or EL0. If this is not done, behavior is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6414.
D4.11 Caches in a VMSAv8-64 implementation

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

In particular, maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and address translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- Data and unified caches.
- Instruction caches.

In addition, Cache maintenance requirement created by changing translation table attributes on page D4-2223 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see A64 Cache maintenance instructions on page D3-2062, that describes the cache maintenance instructions in the A64 instruction set.

D4.11.1 Data and unified caches

For data and unified caches, the use of address translation is entirely transparent to any data access other than as described in Mismatched memory attributes on page B2-125.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as Physically-indexed, physically-tagged (PIPT) caches.

D4.11.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture permits different behaviors for instruction caches. These are identified by descriptions of the associated expected implementation. The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of address translation transparent to the instruction cache:

- PIPT (Physically-indexed, physically-tagged) instruction caches on page D4-2222.
- VPIPT (VMID-aware PIPT) instruction caches on page D4-2222.
- VIPT (Virtually-indexed, physically-tagged) instruction caches on page D4-2222.
- The IVIPT Extension on page D4-2223.

The CTR_EL0.L1Ip field identifies the form of the instruction caches.
**Note**

For software to be portable between implementations that might use any of PIPT instruction caches, VPIPT instruction caches, or VIPT instruction caches, software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

**PIPT (Physically-indexed, physically-tagged) instruction caches**

For a PIPT instruction cache:

- The use of memory address translation is entirely transparent to all instruction fetches other than as described in *Mismatched memory attributes* on page B2-125.

- If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see *The IVIPT Extension* on page D4-2223.

**VPIPT (VMID-aware PIPT) instruction caches**

An ARMv8.2 implementation can implement VPIPT instruction caches. If it does so then it is described as implementing ARMv8.2-VPIPT.

The CTR_EL0.L1Ip field identifies the implemented cache type, meaning it identifies whether ARMv8.2-VPIPT is implemented.

For a VPIPT instruction cache:

- Instruction fetches from Non-secure EL1 and Non-secure EL0 are only permitted to hit in the cache if the instruction fetch is made using the VMID that was used when the entry in the instruction cache was fetched.

- An instruction cache maintenance instruction executed at Non-secure EL0 or at Non-secure EL1 is required to have an effect on entries in the instruction cache only if those entries were fetched using the VMID that is current when the cache maintenance instruction is executed.

All other requirements for the use of cache maintenance instructions are the same as for *PIPT (Physically-indexed, physically-tagged) instruction caches*.

An implementation that provides VPIPT instruction caches implements the IVIPT Extension, see *The IVIPT Extension* on page D4-2223.

**VIPT (Virtually-indexed, physically-tagged) instruction caches**

For a VIPT instruction cache:

- The use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in *Mismatched memory attributes* on page B2-125.

---

**Note**

Cache invalidation is the only cache maintenance that can be performed on an instruction cache.

---

- If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the VA supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a PA from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see *The IVIPT Extension* on page D4-2223.
The IVIPT Extension

In ARMv8, any permitted instruction cache implementation can be described as implementing the IVIPT Extension to the ARM architecture.

The formal definition of the ARM IVIPT Extension is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a PA that holds an instruction.

Note

Previous versions of the ARM architecture have permitted an instruction cache option that does not implement the ARM IVIPT Extension.

D4.11.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in General TLB maintenance requirements on page D4-2207. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through
- Write-Back to Non-cacheable
- Write-Through to Non-cacheable
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from the cache.
3. Change the shareability attributes to the required new values.
This chapter describes the ARMv8 implementation of the ARM Performance Monitors, that are an optional non-invasive debug component. It describes version 3 of the *Performance Monitor Unit* (PMU) architecture, PMUv3. It contains the following sections:

- *About the Performance Monitors* on page D5-2226.
- *Accuracy of the Performance Monitors* on page D5-2228.
- *Behavior on overflow* on page D5-2230.
- *Attributability* on page D5-2232.
- *Effect of EL3 and EL2* on page D5-2233.
- *Event filtering* on page D5-2235.
- *Performance Monitors and Debug state* on page D5-2237.
- *Counter enables* on page D5-2238.
- *Counter access* on page D5-2239.
- *PMU events and event numbers* on page D5-2240.
- *Performance Monitors Extension registers* on page D5-2268.

---

**Note**

Table K13-1 on page K13-6592 disambiguates the general register references used in this chapter.
D5.1 About the Performance Monitors

In ARMv8-A, the Performance Monitors Extension is an optional feature of an implementation, but ARM strongly recommends that ARMv8-A implementations include version 3 of the Performance Monitors Extension, PMUv3.

Note

No previous versions of the Performance Monitors Extension can be implemented in ARMv8.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter, see Time as measured by the Performance Monitors cycle counter on page D5-2227.
- A number of 32-bit event counters. The event counted by each counter is programmable. ARMv8 provides space for up to 31 counters. The actual number of counters is implementation defined, and the specification includes an identification mechanism.

Note

ARM recommends that at least two counters are implemented, and that hypervisors provide at least this many counters to guest operating systems.

- When EL2 is implemented, the required controls to partition the implemented counters into the following sets:
  - A set which is available for use by the guest operating system.
  - A set which is available for use by the hypervisor.

Note

ARMv8.3-NV does not introduce any changes to the Performance Monitors, see Nested virtualization on page D4-2188.

- Controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Enabling interrupts on overflow.

Monitoring software can enable the cycle counter independently of the event counters.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures.

Note

Implementations that include PMUv3 must, as a minimum requirement, implement a subset of the common events. See Common event numbers on page D5-2245.

- Reserves a large event number space for implementation defined events.

The full set of events for an implementation is implementation defined. ARM recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation.

When an implementation includes the Performance Monitors Extension, ARMv8 defines the following possible interfaces to the Performance Monitors Extension registers:

- A System register interface. This interface is mandatory.

Note

In AArch32 state, the interface is in the (coproc==0b1111) encoding space.
D5 The Performance Monitors Extension

D5.1 About the Performance Monitors

• An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See Chapter 13 Recommended External Interface to the Performance Monitors.

An operating system can use the System registers to access the counters.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

• A set of events, from which a selection can be exported onto a bus for use as external events.
• The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Extension is common to AArch64 operation and AArch32 operation. This means the ARMv8 architecture defines both AArch64 and AArch32 System registers to access the Performance Monitors. For example, the Performance Monitors Cycle Count Register is accessible as:

• When executing in AArch64 state, PMCCNTR_EL0.
• When executing in AArch32 state, PMCCNTR.

D5.1.1 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through PMCCNTR_EL0 or PMCCNTR, increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

--- Note ---
• This means that, in an implementation where PEs are multithreaded, the counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.
• Although the architecture requires that direct reads of PMCCNTR_EL0 or PMCCNTR occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

The architecture requires that an indirect write to the PMCCNTR_EL0 or PMCCNTR is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

D5.1.2 Interaction with trace

It is IMPLEMENTATION DEFINED whether the implementation exports counter events to a Trace macrocell, or other external monitoring agent, to provide triggering information. The form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting might be enabled as part of the performance monitoring control functionality.

ARM recommends system designers include a mechanism for importing a set of external events to be counted, but such a feature is IMPLEMENTATION DEFINED. When implemented, this feature enables the Trace macrocell to pass in events to be counted.

D5.1.3 Interaction with power saving operations

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.
D5.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See Non-invasive behavior.
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See A reasonable degree of inaccuracy on page D5-2229.
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to put the PE in an operating state that might do one or both of the following:
  - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
  - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D5.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, PC Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multitasking operating system. As such, a reasonable variation in performance is permissible.

Note

Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

ARM does not define a reasonable variation in performance, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

Note

For profiles other than A-profile, there is the potential for stronger requirements. Ultimately, performance requirements are determined by end-users, and not set by the architecture.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative IMPLEMENTATION DEFINED event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an IMPLEMENTATION DEFINED control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.
D5.2   A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. ARM does not define a reasonable degree of inaccuracy but recommends the following guidelines:

- Under normal operating conditions, the counters must present an accurate value of the count.
- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.
- Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

--- Note ---
An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count.

However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

---

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision.

A change of Security state can also affect the accuracy of the Performance Monitors, see Interaction with EL3 on page D5-2233.

In addition to this, entry to and exit from Debug state can disturb the normal running of the PE, causing further inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can employ methods to limit this inaccuracy, for example by promptly disabling the counters during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.
D5.3 Behavior on overflow

All events are counted in 32-bit wrapping counters, that overflow when they wrap. The cycle counter, PMCCNTR, is a 64-bit wrapping counter, that is configured by PMCR.LC to either:

• Signal an overflow when bit PMCCNTR[63] overflows.
• Signal an overflow when bit PMCCNTR[31] overflows into bit PMCCNTR[32].

On a Performance Monitors counter overflow:

• An overflow status bit is set to 1. See PMOVSCLR.
• An interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see Generating overflow interrupt requests.
• The counter continues counting events.

D5.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See PMINTENSET and PMINTENCLR.

--- Note ---

• The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.

• ARM recommends that the overflow interrupt requests:
  — Translate into a PMUIIRQ signal, so that they are observable to external devices.
  — Connect to inputs on an IMPLEMENTATION DEFINED generic interrupt controller as a Private Peripheral Interrupt (PPI) for the originating processor. See the ARM Generic Interrupt Controller Architecture Specification for information about PPIs.
  — Connect to a Cross Trigger Interface (CTI), see Chapter H5 The Embedded Cross-Trigger Interface.

• ARM strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same System Peripheral Interrupt (SPI) identifier.

• From GICv3, the ARM® Generic Interrupt Controller Architecture Specification recommends that the Private Peripheral Interrupt (PPI) with ID 23 is used for overflow interrupt requests.

Counter overflow when counting one or more events generates an unsigned carry out. Software can write to the counters to control the frequency at which interrupt requests occur. For counters other than the cycle counter, the counter is always a 32-bit unsigned wrapping value. For example, software might set a counter to 0xFFFF0000, to generate another counter overflow after 65536 increments, and reset it to this value every time an overflow interrupt occurs.

--- Note ---

If an event can occur multiple times in a single clock cycle, then counter overflow can occur without the counter registering a value of zero.

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

• Any given PMN\textsubscript{x} counter, when the value of PMOVSET[\textsubscript{x}] is 1, the value of PMINTENSET[\textsubscript{x}] is 1, and one of the following is true:
  — EL2 is not implemented and the value of PMCR.E is 1.
  — EL2 is implemented, \textsubscript{x} is less than the value of HDCR.HPMN, and the value of PMCR.E is 1.
  — EL2 is implemented, \textsubscript{x} is greater than or equal to the value of HDCR.HPMN, and the value of HDCR.HPME is 1.

• The cycle counter, when the values of PMOVSET[31], PMINTENSET[31], and PMCR.E are all 1.
The overflow interrupt request is active in both Secure and Non-secure states. In particular, if EL3 and EL2 are both implemented, overflow events from PMN\textsubscript{x} where \( x \) is greater than or equal to the value of HDCR.HPMN can be signaled from all modes and states but only if the value of HDCR.HPME is 1.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing to PMOVSCLR\[x\] to clear the overflow bit to 0.

**Pseudocode description of overflow interrupt requests**

See Chapter J1 *ARMv8 Pseudocode* for a pseudocode description of overflow interrupt requests. The AArch64.CheckForPMUOverflow() and AArch32.CheckForPMUOverflow() pseudocode functions signal PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface.
D5.4 Attributability

An event caused by the PE counting the event is Attributable. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Security state of the PE.
- The current Exception level of the PE.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multithreaded implementation, an event might be Attributable either to the current Exception level alone, or to both the Exception level and the Security state of another PE with the same values for affinity level 1 and higher.

Note

An implementation is described as multithreaded when the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. In this section, when referring to a multithreaded implementation, thread is used to mean processing elements with different affinity level 0 values and the same values for affinity level 1 and higher.

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are Attributable, unless otherwise stated.

Unattributable events might be counted when Attributable events are not counted. See:

- Interaction with EL3 on page D5-2233.
- Event filtering on page D5-2235.
- Performance Monitors and Debug state on page D5-2237.

These sections are summarized by Table D5-1 for events Attributable to the processor, and Unattributable events.

D5.5 Effect of EL3 and EL2

This section describes the effects of implementing EL3 and EL2 on the Performance Monitors. It contains the following subsections:

- **Interaction with EL3**
- **Interaction with EL2** on page D5-2234.

D5.5.1 Interaction with EL3

While counting events is never prohibited in Non-secure state, there are some restrictions on counting events in Secure state. From reset, counting events Attributable to Secure state is prohibited in Secure state. When executing in AArch32 state, software can set SDCR.SPME to 1 to permit event counting in Secure state. In AArch64 state, software can set MDCR_EL3.SPME to 1 to permit event counting in Secure state.

**Note**

This enables a Secure Monitor to permit profiling within Secure state without having to configure an IMPLEMENTATION DEFINED debug authentication interface.

The system can use the external authentication interface to override SPME.

If EL3 is not implemented, the behavior is as if the value of SDCR.SPME or MDCR_EL3.SPME is 1, as appropriate.

Counting Attributable events in Secure state is prohibited unless any one of the following is true:

- EL3 is not implemented.
- EL3 is implemented, is using AArch64, and the value of MDCR_EL3.SPME is 1.
- EL3 is implemented, is using AArch32, and the value of SDCR.SPME is 1.
- EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0, and the value of SDER32_EL3.SUNIDEN is 1.
- In ARMv8.0 and ARMv8.1 implementations, EL3 is implemented, and counting is permitted by an IMPLEMENTATION DEFINED authentication interface, ExternalSecureNoninvasiveDebugEnabled() == TRUE.

**Note**

Software can read the Authentication Status register, DBGAUTHSTATUS, to determine the state of an IMPLEMENTATION DEFINED authentication interface.

Software executing at EL3 can trap attempts by lower Exception levels to access the PMU. This means that the Secure monitor can identify any software which is using the PMU and switch contexts, if required.

The cycle counter, PMCCNTR, counts even when event counting is prohibited, unless PMCR.DP is set to 1 or the PE is in Debug state.

The Performance Monitors registers are always accessible regardless of the values of the authentication signals and the SDER.SUNIDEN bit. Authentication controls whether the counters count events, it does not control access to the Performance Monitors registers.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when counting Attributable events is prohibited.

**Note**

- Additional controls in PMCR, HDCR, PMCNTENSET, and PMCNTENCLR can also disable the event counters and the cycle counter.
- Controls in PMEVTYPE<\text{n}> and PMCCFILTR can also disable counting based on Exception level and Security state.
See `AArch64.CountEvents()` and `AArch32.CountEvents()` in Chapter J1 *ARMv8 Pseudocode* for more information. The `CountEvents()` functions return `TRUE` if `PMN` counts events or the cycle counter counts cycles at the current Exception level and state. However, these functions do not completely describe the behavior for Unattributable events.

In AArch32 state, the Performance Monitors registers are Common registers, see *Classification of System registers* on page G4-4972.

The Performance Monitors are intended to be broadly accurate and statistically useful, see *Accuracy of the Performance Monitors* on page D5-2228. Some inaccuracy is permitted at the point of changing Security state, however. To avoid the leaking of information from the Secure state, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

**Multithreaded implementations**

If an implementation is multithreaded and the value of `PMEVTYPER<ν>.MT == 1`, then the PE does not count an event that is Attributable to Secure state on another thread if counting events Attributable to Secure state is prohibited in Secure state on the PE that is counting the events.

**Example D5-1 The effect of having PMEVTYPER<ν>.MT == 1**

If the value of `MDCR_EL3.SPME` is 0 on one thread, then it does not count events Attributable to Secure state on another thread, even if one or both of the following applies:

- This thread is in Non-secure state.
- `MDCR_EL3.SPME==1` on the other thread.

Otherwise:

- When the current configuration prohibits counting of events Attributable to Secure state in Secure state, it is IMPLEMENTATION DEFINED whether:
  - Counting events Attributable to Secure state on this PE in Non-secure state is permitted.
  - Counting Unattributable events related to other secure operations in the system is permitted.
- Otherwise, counting events in Non-secure state is permitted.

**D5.5.2 Interaction with EL2**

In an implementation that includes EL2, Non-secure software executing at EL2 can:

- Trap any attempt by the Guest OS to access the PMU. This means the hypervisor can identify which Guest OSes are using the PMU and intelligently employ switching of the PMU state.
- Trap accesses to the `PMCR`, so that it can fully virtualize the PMU identity registers, `PMCR.IMP` and `PMCR.IDCODE`.
- Reserve the highest-numbered counters for its own use by overriding the value of `PMCR.N` seen by the Guest OS. The PE does not permit a Guest OS to access the reserved counters.

`HDCR` controls Performance Monitors virtualization.

- *Counter enables on page D5-2238.*
- *Counter access on page D5-2239.*
D5.6 Event filtering

The PMU can filter events by various combinations of Exception level and Security state. This gives software the flexibility to count events across multiple processes.

D5.6.1 Filtering by Exception level and PE state

In AArch64 state:

- For each event counter PMEVTYPER\(<n>\)_EL0 specifies the Exception levels in which the counter counts events Attributable to Exception levels.
- PMCCFILTR_EL0 specifies the Exception levels in which the cycle counter counts.

In an implementation that supports multithreading:

- When the value of PMEVTYPER\(<n>\)_EL0.MT is 1, if an event is Attributable to another thread, then the specified filtering applies to the current Exception level and PE state of the thread to which the event is attributable, regardless of the Exception level and state of the counting thread.
- When the value of PMEVTYPER\(<n>\)_EL0.MT is 0, the event only counts events that are attributable to the counting thread, and the filtering applies to the Exception level and PE state of the counting state, see Example D5-2.

Example D5-2 Example of the effect of the PMEVTYPER\(<n>\)_EL0.MT control

If the value of PMEVTYPER\(<n>\)_EL0.U is 0 on the current thread, then it does not count events Attributable to EL0 on the other thread, even if this thread is not executing at EL0.

Otherwise, for each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies.

In AArch32 state, the filtering controls are provided by the PMEVTYPER\(<n>\) and PMCCFILTR registers.

For more information, see the individual register descriptions.

Reserved combinations of the filtering controls

The filtering controls are provided by the \{P, U, NSK, NSU, NSH, M\} fields of the controlling register, PMEVTYPER\(<n>\)_EL0, PMCCFILTR_EL0, PMEVTYPER\(<n>\), or PMCCFILTR.

Some combinations of these fields select filtering options that do not represent a meaningful use case, and therefore these cases are reserved. Table D5-2 shows these reserved filtering encodings.

<table>

a. Software must not program the counter to count at EL0 in one state and at EL1 in the other state.
The reserved filtering encodings shown in Table D5-2 on page D5-2235 are not UNPREDICTABLE and are not CONstrained UNPREDICTABLE. Implementations must implement the filtering controls as described in the appropriate register descriptions.

D5.6.2 Accuracy of event filtering

The PMU architecture does not require event filtering to be accurate.

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- Exception-related events.
- Software increment events.

Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level in which the event occurred. These events are:

- EXC_TAKEN, Exception taken.
- EXC_RETURN, Instruction architecturally executed, Condition code check pass, exception return.
- CID_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR.
- TTBR_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to translation table base.

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to CONTEXTIDR after the return from the exception.

Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any Speculatively executed software increment.

Software increment events must also be counted without the need for explicit synchronization. For example, two software increments executed without an intervening Context synchronization event must increment the event counter twice.

For more information, see SW_INCR, Instruction architecturally executed, Condition code check pass, software increment.

Pseudocode description of event filtering

See AArch64.CountEvents() and AArch32.CountEvents() in Chapter J1 ARMv8 Pseudocode for a pseudocode description of event filtering. However, this function does not completely describe the behavior for Unattributable events.
D5.7 Performance Monitors and Debug state

Events that count cycles are not counted in Debug state.

Events Attributable to the operations issued by the debugger through the external debug interface are not counted in Debug state.

In an implementation that supports multithreading, when the value of PMEVTYPE[n>].EL0.MT is 1, if an event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is IMPLEMENTATION DEFINED whether the event is counted when the counting thread is in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting PE is in Debug state. If the event might be counted, then the rules in Filtering by Exception level and PE state on page D5-2235 apply for the current Security state in Debug state.
D5.8 Counter enables

Table D5-3 shows an implementation that does not include EL2, and where the PMCR.E bit is a global counter enable bit, and PMCNTENSET provides an enable bit for each counter.

<table>
<thead>
<tr>
<th>PMCR.E</th>
<th>PMCNTENSET[x] == 0</th>
<th>PMCNTENSET[x] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PMNr disabled</td>
<td>PMNr disabled</td>
</tr>
<tr>
<td>1</td>
<td>PMNr disabled</td>
<td>PMNr enabled</td>
</tr>
</tbody>
</table>

If the implementation includes EL2, then in addition to the PMCR.E and PMCNTENSET enable bits:
- HDCR.HPME overrides the value of PMCR.E for counters configured for access in Hyp mode.
- HDCR.HPMN specifies the number of performance counters that the Guest OS can access. The minimum permitted value of HDCR.HPMN is 1, meaning there must be at least one counter that the Guest OS can access.

Table D5-4 shows the combined effect of all the counter enable controls.

<table>
<thead>
<tr>
<th>HDCR.HPME</th>
<th>PMCR.E</th>
<th>PMCNTENSET[x] == 0</th>
<th>PMCNTENSET[x] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>PMNr disabled</td>
<td>PMNr disabled</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>PMNr disabled</td>
<td>PMNr enabled</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>PMNr disabled</td>
<td>PMNr enabled</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>PMNr disabled</td>
<td>PMNr enabled</td>
</tr>
</tbody>
</table>

--- Note ---

The effect of HDCR.{HPME, HPMN} on the counter enables applies in both Security states. However, in Secure state the value returned for PMCR.N is not affected by HDCR.HPMN.

EL2 does not affect the enabling of PMCCNTR. Table D5-5 shows the PMCCNTR enables, for all implementations.

<table>
<thead>
<tr>
<th>PMCR.E</th>
<th>PMCNTENSET[31] == 0</th>
<th>PMCNTENSET[31] == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PMCCNTR disabled</td>
<td>PMCCNTR disabled</td>
</tr>
<tr>
<td>1</td>
<td>PMCCNTR disabled</td>
<td>PMCCNTR enabled</td>
</tr>
</tbody>
</table>
D5.9 Counter access

All implemented counters are accessible in EL3, Secure EL1 and EL2. If EL2 is implemented the hypervisor uses HDCR.HPMN to reserve an event counter, with the effect that software cannot access that counter and its associated state from Non-secure EL1 or from Non-secure EL0.

Note

This section describes a counter as being accessible from a particular Exception level and state. However, access to the registers is subject to the access permissions described in Access permissions on page D5-2268. In particular, accesses from EL0 might be UNDEFINED and accesses might be trapped to EL1 or EL2.

D5.9.1 PMNx event counters

For an implementation that includes EL2 and EL3, Table D5-6 shows how the values of the HDCR.HPMN field control the behavior of accesses to the PMNx event counter registers.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL3</td>
<td>EL1</td>
</tr>
<tr>
<td>x &lt; HDCR.HPMN</td>
<td>Succeeds</td>
<td>Succeeds</td>
</tr>
<tr>
<td>x ≥ HDCR.HPMN</td>
<td>Succeeds</td>
<td>Succeeds</td>
</tr>
</tbody>
</table>

Where Table D5-6 shows no access:

- If PMSEL.R.SEL is x then:
  - A direct read of PMXEVTYPER or PMXEVCNTR is CONSTRAINED UNPREDICTABLE.
  - A direct write to PMXEVTYPER or PMXEVCNTR is CONSTRAINED UNPREDICTABLE.

- A direct read of PMEVTYPER<\n> or PMEVCNTR<\n> is CONSTRAINED UNPREDICTABLE.

- A direct write of PMEVTYPER<\n> or PMEVCNTR<\n> is CONSTRAINED UNPREDICTABLE.

- For direct reads and direct writes, PMOVSCLR[x], PMOVSSET[x], PMCNTENSET[x], PMCNTENCLR[x], PMINTENSET[x], and PMINTENCLR[x] are RAZ/WI.

- Direct writes to PMSWINC[x] are ignored.

- A direct write of 1 to PMCR.P does not reset PMNx.

For more information on the CONSTRAINED UNPREDICTABLE behavior of the Performance Monitor Extension, see:

- For AArch32, The Performance Monitors Extension on page K1-6397.
- For AArch64, The Performance Monitors Extension on page K1-6415.

Note

In Secure state, and in the Non-secure EL2 mode, the value of HDCR.HPMN does not affect the value returned for PMCR.N.

D5.9.2 Cycle counter

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. The only control over the cycle counter is an access permission control for EL0. See Access permissions on page D5-2268.
D5.10 PMU events and event numbers

The following sections describe the events that can be counted and their associated event numbers, and the mnemonics for the events:

- Definitions.
- The PMU event number space and common events on page D5-2244.
- Common event numbers on page D5-2245.
- Statistical Profiling Extension microarchitectural events on page D5-2263.
- Cycle event counting on multithreaded implementations on page D5-2264.
- Meaningful ratios between common microarchitectural events on page D5-2265.
- Required events on page D5-2266.
- IMPLEMENTATION DEFINED event numbers on page D5-2266.

D5.10.1 Definitions

The following subsections give more information about terms used in the event definitions:

- Definition of terms.
- Levels of caches and TLBs on page D5-2243.
- Shared caches and buses on page D5-2243.

Definition of terms

Speculatively executed

Many events relate to speculatively executed operations. Here, speculatively executed means the PE did some work associated with one or more instructions but the instructions were not necessarily architecturally executed.

An instruction might create one or more microarchitectural operations (micro-ops) at any point in the execution pipeline. For the purpose of event counting, the micro-ops are counted. The definition of a micro-op is implementation specific. An architecture instruction might create more than one micro-op for each instruction. micro-ops might also be removed or merged in the execution stream, so an architecture instruction might create no micro-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of micro-ops is permitted.

This means there is no architecturally guaranteed relationship between a speculatively executed micro-op and an architecturally executed instruction. The results of such an operation can also be discarded, if it transpires that the operation was not required, such as a mispredicted branch.

Therefore, ARMv8-A defines these events as operation speculatively executed, where appropriate.

Note

The definition of speculatively executed does not mean only those operations that are executed speculatively and later abandoned, for example due to a branch misprediction or fault. That is, speculatively executed operations must count operations on both false and correct execution paths.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

For example, an implementation might split an A32 or T32 LDM instruction of six registers into six micro-ops, one for each load, and a seventh address-generation operation to determine the base address or writeback address. Also, for doubleword alignment, the six load micro-ops might combine into four operations, that is, a word load, two doubleword loads, and a second word load. This single instruction can then be counted as five, or possibly six, events:

- Four (Operation speculatively executed - Load) events.
- One (Operation speculatively executed - Integer data processing) event.
- One (Operation speculatively executed - Software change of the PC) event if the PC was one of the six registers in the LDM instruction.
Different groups of events can have different implementation defined definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed. For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Within these groups, events are commonly defined with reference to a particular architecture instruction or group of instructions. In the case of speculatively executed operations this means operations with semantics that map to that type of instruction.

**Instruction memory access**

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction preload instruction, PLI.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is implementation defined. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

**Memory-read operations**

A PE accesses memory through memory-read operations and memory-write operations. A memory-read operation might be due to:

- The result of an architecturally executed memory-reading instructions.
- The result of a speculatively executed memory-reading instructions.
- A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:

- Memory-read operations or memory-write operations that miss in the cache
- The execution of a data preload instruction.
- The execution of an instruction preload instruction on a unified cache.
- The execution of a cache maintenance instruction.

--- Note ---

A preload instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

- Speculation that a future instruction might access the memory location.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is implementation defined. For example, for some implementations an LDP instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.
Memory-write operations

Memory-write operations might be due to:

- The result of an architecturally executed memory-writing instructions.
- The result of a Speculatively executed memory-writing instructions.

Note

Speculatively executed memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation specific way.

For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see Memory-read operations.
- The execution of a cache maintenance instruction.

Note

A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as memory-write operations beyond that cache.

- The result of a coherency request from another PE.

This list is not exhaustive.

The relationship between memory-writing instructions and memory-write operations is IMPLEMENTATION DEFINED. For example, for some implementations an STP instruction that writes two 64-bit registers might generate one memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more memory-write operations. In some implementations, the result of two STR instructions that write to adjacent memory might be merged into a single memory-write operation.

Note

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

Instruction architecturally executed

Instruction architecturally executed is a class of event that counts for each instruction of the specified type. Architecturally executed means that the program flow is such that the counted instruction would be executed in a Simple sequential execution of the program. Therefore an instruction that has been executed and retired is defined to be architecturally executed. When a PE can perform speculative execution, an instruction is not architecturally executed if the PE discards the results of the speculative execution.

If an instruction that would be executed in a Simple sequential execution of the program generates a synchronous exception, it is IMPLEMENTATION DEFINED whether the instruction is counted.

Each architecturally executed instruction is counted once, even if the implementation splits the instruction into multiple operations. Instructions that have no visible effect on the architectural state of the PE are architecturally executed if they form part of the architecturally executed program flow. The point where such instructions are retired is IMPLEMENTATION DEFINED.

Examples of instructions that have no visible effect are:

- A NOP.
- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.

The point at which an event causes an event counter to be updated is not defined.
Unless otherwise stated, all instructions of the specified type are counted even if they have no visible effect on the architectural state of the PE. This includes a conditional instruction that fails its Condition code check.

For events that count only the execution of instructions that update context state, such as writes to the CONTEXTIDR, if such an instruction is executed twice without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first instruction is counted.

**Instruction architecturally executed, Condition code check pass**

*Instruction architecturally executed, Condition code check pass* is a class of events that explicitly do not occur for:

- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.
- A Test and Branch on Zero, TBZ, instruction that does not branch.
- A Test and Branch on Nonzero, TBNZ, instruction that does not branch.
- A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for *Instruction architecturally executed*.

**Levels of caches and TLBs**

The mapping of different levels of cache or TLB to the PMU events is determined by the implementation. Although the CLIDR_EL1, or the AArch32 CLIDR, defines the implemented levels of cache, the architecture does provide any way of determining implemented levels of TLB. Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The implementation-specific nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations.

**Shared caches and buses**

There is no architectural concept of a *shared* component. However, when a cache, a bus, or any other system component that might generate countable events is implemented, and:

- The extent of the first-order effects due to an event from that component are only applicable to a single PE, then the event is not shared.
- Otherwise, the event is shared.

Second-order effects are not considered when determining if an event is shared.

**Example D5-3 First and second order effects of a cache miss in a multiple-PE implementation**

In an implementation that consists of two PEs, each with its own L1 cache, a cache miss by one of the PEs is a first-order effect of an access to its cache. Any snoop that is performed on the L1 cache of the other PE in the implementation as a result of that cache miss is a second order effect.

--- **Note** ---

Shared events are inherently linked to microarchitectures and so the implementer must make an informed decision about how such events are implemented.
### The PMU event number space and common events

In ARMv8.0, the event number space is 10 bits. ARMv8.1 extends the event number space, and therefore the PMEVTYPER<sup>HE</sup> EL0.evtCount field to 16 bits, and is allocated as Table D5-7 shows. For more information about the entries in the Allocation column see the text that follows this table:

<table>
<thead>
<tr>
<th>Event numbers</th>

<td>Reserved.</td>
</tr>
<tr>
<td>0xC0C0-0xFFFF</td>
<td>IMPLEMENTATION DEFINED events.</td>
</tr>
</tbody>
</table>

The meaning of the entries in the Allocation column of Table D5-7 is as follows:

**Common architectural and microarchitectural events**

ARM defines the use of these event numbers. For more information see Common event numbers on page D5-2245.

**ARM-recommended common architectural and microarchitectural events**

The use of these event numbers is IMPLEMENTATION DEFINED. For more information see:

- IMPLEMENTATION DEFINED event numbers on page D5-2266.
- Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events.

**IMPLEMENTATION DEFINED event numbers**

For more information about the use of these event numbers see IMPLEMENTATION DEFINED event numbers on page D5-2266.
D5.10.3 Common event numbers

The event numbers of the common architectural and microarchitectural events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

However, see Required events on page D5-2266.

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, ARM strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from an IMPLEMENTATION DEFINED range.

--- Note ---

ARM might define other common architectural and microarchitectural event numbers. This is one reason why software must not assume that an event with an assigned common architectural or microarchitectural event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

Table D5-8 lists the PMU common architectural and microarchitectural event numbers in event number order. The entries in the Event mnemonic column link to the event description in Common architectural events on page D5-2248 or Common microarchitectural events on page D5-2252.

</table>
The supported common architectural and microarchitectural events are identified by:

- The PMCEID0_EL0 and PMCEID1_EL0 registers in AArch64 state.
- The PMCEID0, PMCEID1, PMCEID2, and PMCEID3 registers in AArch32 state.

ARM recommends that the value of 0 is used for the PMCEID0_EL0 or PMCEID1_EL0 bit corresponding to any event that an implementation never generates, even if the implementation is considered to support but never count the event.

**Note**

- For example, if an implementation never generates the L1D_CACHE_ALLOCATE event, event 31, ARM recommends that PMCEID0_EL0[31] is RAZ.
- In an implementation that supports both Execution states, each bit in the AArch64 PMCEID0_EL0 and PMCEID1_EL0 registers corresponds to a single bit in the AArch32 PMCEID0, PMCEID1, PMCEID2, and PMCEID3 registers, and corresponding bits must have the same behavior.

However, for some implementations, an event in the common events range might be generated by the system, meaning behavior can vary between systems. In such a case, the corresponding PMCEIDn_EL0 bit might be RAO.

Event numbers that Table D5-7 on page D5-2244 shows as allocated for common architectural and microarchitectural events that are not shown in Table D5-8 on page D5-2245 are reserved. Future revisions of this manual, or of the architecture, might assign these reserved values to additional common events. Events that do not
require additional features in the PMU can be implemented retrospectively, meaning an implementation of a particular version of the PMU specification might support common events that are first defined in a later version of the PMU specification.

--- Note ---

- The requirement that an event that is implemented retrospectively does not require additional features in the PMU means that it must be possible to represent the event in the PMEVTYPER<n>_EL0.evtCount field. This means, for example, that an implementation with a 12-bit PMEVTYPER<n>_EL0.evtCount field can only implement events with event numbers 0x000-0xFFF.

- This means that, for example, an ARMv7 PMUv2 implementation, for which the evtCount field is 8 bits, can include support for any of the event numbers that Table D5-8 on page D5-2245 defines in the range 0x000-0xFFF.

Common architectural events

This section describes the use of the defined common architectural event numbers.

For the common features, normally the counters must increment only once for each event. The event descriptions include any exceptions to this rule.

In these definitions, the term architecturally executed means that the instruction flow is such that the counted instruction would have been executed in a Simple sequential execution model.

The events corresponding to the common architectural event numbers are:

0x0000, SW_INCR, Instruction architecturally executed, Condition code check pass, software increment

The counter increments on writes to the PMSWINC register.

If the PE performs two architecturally executed writes to the PMSWINC register without an intervening Context synchronization event, then the counter is incremented twice.

If PMEVTYPER<n>_EL0.evtCount is set to 0x000, then in AArch64 state, counts MSR writes to PMSWINC_EL0 with bit [n] set to 1.

If the value of PMEVTYPER<n>_EL0.MT is 1 then, in a multithreaded implementation, this counts writes by all PEs that have the same affinity at level 1 and above.

0x0006, LD_RETIRED, Instruction architecturally executed, Condition code check pass, load

The counter increments for every executed memory-reading instruction.

--- Note ---

This event 0x006 does not count the return status value of a Store-Exclusive instruction.

Whether the preload instructions PRFM, PLD, PLDW, PLI, count as memory-reading instructions is IMPLEMENTATION DEFINED. ARM recommends that if the instruction is not implemented as a NOP then it is counted as a memory-reading instruction.

0x0007, ST_RETIRED, Instruction architecturally executed, Condition code check pass, store

The counter increments for every executed memory-writing instruction.

DC ZVA is counted as a store.

The counter does not increment for a Store-Exclusive instruction that fails.

0x0008, INST_RETIRED, Instruction architecturally executed

The counter increments for every architecturally executed instruction.

0x0009, EXC_TAKEN, Exception taken

The counter increments for each exception taken. See Exception-related events on page D5-2236.
Note
The counter counts the PE exceptions described in:
- For exceptions taken to an Exception level using AArch64, Exception entry on page D1-1874.
- For exceptions taken to an Exception level using AArch32, AArch32 state exception descriptions on page G1-4661.

0x000A, EXC_RETURN, Instruction architecturally executed, Condition code check pass, exception return
The counter increments for each executed exception return instruction. See also Exception-related events on page D5-2236. The following sections define the counted instructions:
- For an exception return from an Exception level using AArch64, Exception return on page D1-1883.
- For an exception return from an Exception level using AArch32, Exception return instructions on page G1-4645.

However, is CONSTRAINED UNPREDICTABLE whether this event counts the execution of an exception return instruction if either:
- Execution of the instruction is, itself, CONSTRAINED UNPREDICTABLE.

Note
Examples of when an exception return instruction is CONSTRAINED UNPREDICTABLE are if the instruction is executed at EL0, or in AArch32 state in System mode.

- Execution of the instruction sets PSTATE.IL and does not generate an exception return.

Note
A particular consequence of this CONSTRAINED UNPREDICTABLE behavior is that an implementation that does not support AArch32 state at EL1 or higher does not have to treat AArch32 MOV PC, LR instructions, and related instructions, as exception return instructions.

0x000B, CID_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR
The counter increments for every write to CONTEXTIDR. See Exception-related events on page D5-2236.

If the PE performs two architecturally-executed writes to CONTEXTIDR without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

When ARMv8.1-VHE is implemented, the counter is:
- Incremented as a result of the retirement of an instruction accessing the named register CONTEXTIDR_EL1, even when executing at EL2.
- Not incremented as a result of the retirement of an instruction accessing the named CONTEXTIDR_EL2.

Note
The event is defined by the name used to access the register. The counter does not count writes to the named register CONTEXTIDR_EL2.

0x000C, PC_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, software change of the PC
The counter increments for every software change of the PC. This includes all:
- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions, ERET and RET.

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:
- BRK and BKPT instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, SVC, HVIC, and SMIC.

It is IMPLEMENTATION DEFINED whether an ISB is counted as a software change of the PC.

The counter does not increment for exceptions other than those explicitly identified in these lists.

--- Note ---
Conditional branches are only counted if the branch is taken.

0x000D, **BR_IMMED_RETIRED, Instruction architecturally executed, immediate branch**

The counter counts all immediate branch instructions that are architecturally executed.

In AArch32 state, the counter increments each time the PE executes one of the following instructions:
- B{<c>} <label>.
- BL{<c>} <label>.
- BLX{<c>} <label>.
- CBZ <Rn>, <label>.
- CBNZ <label>.

In AArch64 state, the counter increments each time the PE executes an immediate branch instructions:
- B <label>.
- B.cond <label>.
- BL <label>.
- CBZ <Rn>, <label>.
- CBNZ <Rn>, <label>.
- TBZ <Rn>, <label>.
- TBNZ <Rn>, <label>.

--- Note ---
Conditional branches are always counted, regardless of whether the branch is taken.

If an ISB is counted as a software change of the PC instruction, then it is IMPLEMENTATION DEFINED whether an ISB is counted as an immediate branch instruction.

0x000E, **BR_RETURN_RETIRED, Instruction architecturally executed, Condition code check pass, procedure return**

In AArch32 state, the counter counts the following procedure return instructions:
- BX R14.
- MOV PC, LR.
- POP {..., PC}.
- LDR PC, [SP], #offset.

--- Note ---
The counter counts only the listed instructions as procedure returns. For example, it does not count the following as procedure return instructions:
- BX R0, because Rm != R14.
- MOV PC, R0, because Rm != R14.
- LDM SP, {..., PC}, because writeback is not specified.
In AArch64 state, the counter counts all architecturally executed RET instructions.

0x000F, UNALIGNED_LDSRET_RETIRED, Instruction architecturally executed, Condition code check pass, unaligned load or store

The counter counts each memory-reading instruction or memory-writing instruction access that would generate an Alignment fault when Alignment fault checking is enabled.

This event does not count accesses that would generate an SP alignment fault exception if the applicable stack pointer alignment check is enabled, unless that access would also generate an Alignment fault Data Abort exception if Alignment fault checking is enabled.

It is IMPLEMENTATION DEFINED whether this event counts accesses that generate an exception, including accesses that do generate Alignment fault Data Abort exceptions.

See SP alignment checking on page D1-1868 for more information.
See Unaligned data access on page E2-3027 for more information.

0x001C, TTBR_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to TTBR

The counter counts writes to TTBR0_EL1 and TTBR1_EL1 in AArch64 state and TTBR0 and TTBR1 in AArch32 state. When EL3 is implemented and using AArch32, this includes counting writes to both banked copies of TTBR0 and TTBR1. See Exception-related events on page D5-2236.

If the PE executes two writes to the same TTBR, without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first write to the TTBR, is counted.

If EL3 is implemented and using AArch64, the counter does not count writes to TTBR0_EL3.

If EL2 is implemented and using AArch64, the counter does not count writes to TTBR0_EL2 and to VTTBR_EL2.

If EL2 is implemented and using AArch32, the counter does not count writes to HTTBR and to VTTBR.

When ARMv8.1-VHE is implemented, the counter is:

- Incremented as a result of the retirement of an instruction accessing the named registers TTBR0_EL1 and TTBR1_EL1.
- Not incremented as a result of the retirement of an instruction accessing the named registers TTBR0_EL12 and TTBR1_EL12.

0x001E, CHAIN

For an odd-numbered counter, increments when an overflow occurs on the preceding even-numbered counter on the same PE. Even-numbered counters never increment as a result of this event. This means the CHAIN event links the odd-numbered counter with the preceding even-numbered counter to provide a 64-bit counter.

Note

- The CHAIN event means a system can provide \( N \) 32-bit counters, \( N/2 \) 64-bit counters, or a mixture of 32-bit counters and 64-bit counters.
- The CHAIN event only counts overflows from the preceding even-numbered counter on the same PE. This means it is unaffected by the value of PMEVTPYPER<\( n \)>_EL0.MT.

To filter the Exception levels and Security states in which the event is counted, software must:

- Program PMEVTPYPER<\( n \)>_EL0 to count the event in the required conditions.
- Program PMEVTPYPER<\( n+1 \)>_EL0 to count the CHAIN event in all Exception levels and states.

This allows, (but does not require) hardware to ignore the filter settings for the CHAIN event and behave as if they are set to count in all Exception levels and states.
If software does not program the event in this way, the count becomes **UNPREDICTABLE**.

There is no atomic access to a pair of counters, so if software reads a counter-pair that is enabled, it must use a high-low-high read sequence, or employ reasonable heuristics, to avoid tearing. Similarly, if using CHAIN events, when disabling the counters software must take care that the result is not torn by the low counter overflowing at the same time as the counters are disabled. Example D5-4 shows suitable sequences for disabling and enabling CHAIN counters.

**Example D5-4 Usage examples for 64-bit counters**

An example high-low-high read sequence for a 64-bit counter is:

MRS W2,PMEOCNTR1_EL0 ;; read high counter, must be odd-numbered
retry:
ISB ;; force ordering
MRS W0,PMEOCNTR0_EL0 ;; read low counter
;; must return the previous counter to PMEOCNTR1_EL0
ISB ;; force ordering
MRS W1,PMEOCNTR1_EL0 ;; read high counter
CMP W1,W2
BNE retry ;; if the high counter has changed, then retry

When disabling a pair of counters that are paired by a CHAIN event, software must:

1. Disable the low counter, by setting PMCNTENCLR_EL0[n] to 1.
   Typically, software uses a read-modify-write sequence to update PMCNTENCLR_EL0.
2. Execute an ISB instruction, or perform another Context synchronization event.
3. Disable the high counter, by setting PMCNTENCLR_EL0[n+1] to 1, or setting PMCR_EL0.E to 0.

When enabling a pair of counters that are paired by a CHAIN event, software must:

1. Enable the high counter, by setting PMCNTENCLR_EL0[n+1] to 0 and, if necessary, setting PMCR_EL0.E to 1.
2. Execute an ISB instruction, or perform another Context synchronization event.
3. Enable the low counter by setting PMCNTENCLR_EL0[n] to 0.

When using 64-bit counters, the architecture does not define the latency between the first counter overflowing and the second counter incrementing the CHAIN event. There is no requirement for updates to occur synchronously, but software reading or enabling the counter pair using a low-ISB-high sequence, as shown in Example D5-4, must not observe the low counter incrementing and overflowing for the event and the high counter not incrementing for the resulting CHAIN event. This means that the ISB executed after reading the low counter must ensure the completion of the update of the high counter by the CHAIN event.

**0x0021, BR_RETIRED, Instruction architecturally executed, branch.** The counter counts all branches on the architecturally executed path that would incur cost if mispredicted.

- Counts all branch instructions, memory-reading and data-processing instructions that explicitly write to the PC, at retirement.
- Counts both taken and not-taken branches.
- It is implementation defined whether this includes each of:
  - Unconditional direct branch instructions.
  - Exception-generating instructions.
  - Exception return instructions.
  - Context synchronization instructions.

**Common microarchitectural events**

This section describes the use of the defined common microarchitectural event numbers.
The common microarchitectural events are features that are likely to be implemented across a wide range of implementations. Unlike the common architectural events, there can be some IMPLEMENTATION DEFINED variation between definitions on different implementations.

Unless otherwise stated, the common microarchitectural features relate only to events resulting from the operation of the PE counting the events. Events resulting from the operation of other PEs that might share a resource must not be counted. Where a resource can be subject to events that do not result from the operation of any of the PEs that share it, ARM recommends that the resource implements its own event counters. An example of a resource that might require its own event counters is a shared Level 2 cache that is subject to accesses from a system coherency port on that cache.

The event definitions relating to Level 2 caches generally assume the Level 2 cache is shared. The event definitions relating to Level 1 caches generally assume the Level 1 cache is not shared.

The events corresponding to the common microarchitectural event numbers are:

0x0001, **L1I_CACHE_REFILL, Attributable Level 1 instruction cache refill**

The counter counts Attributable instruction memory accesses that cause a refill of at least the Level 1 instruction or unified cache. This includes each Instruction memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count cache maintenance instructions.

See also:

- *Attributability* on page D5-2232.
- *Meaningful ratios between common microarchitectural events* on page D5-2265.

0x0002, **L1I_TLB_REFILL, Attributable Level 1 instruction TLB refill**

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 1 instruction TLB. This includes each Instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching.

It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- *Attributability* on page D5-2232.
- *Meaningful ratios between common microarchitectural events* on page D5-2265.

0x0003, **L1D_CACHE_REFILL, Attributable Level 1 data cache refill**

The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that causes a refill of at least the Level 1 data or unified cache from outside the Level 1 cache. Each access to a cache line that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and PUSH and POP instructions. In particular, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by another Level 1 data or unified cache, or a Level 2 cache, or memory.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count:

- Accesses that do not cause a new Level 1 cache refill but are satisfied from refilling data of a previous miss.
Accesses to a cache line that generate a memory access but not a new linefill, such as write-through writes that hit in the cache.

Cache maintenance instructions.

A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 cache, for example:
- A write of a full cache line from a coalescing buffer.
- A DC ZVA operation.

A write that misses in the cache, and writes through the cache without allocating a line.

See also:
- Attributability on page D5-2232.
- Meaningful ratios between common microarchitectural events on page D5-2265.

0x0004, L1D_CACHE, Attributable Level 1 data cache access

The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that causes a cache access to at least the Level 1 data or unified cache. Each access to a cache line is counted including the multiple accesses of instructions, such as LDM or STM. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count cache maintenance instructions.

See also Attributability on page D5-2232.

0x0005, L1D_TLB_REFILL, Attributable Level 1 data TLB refill

The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that causes a TLB refill of at least the Level 1 data or unified TLB. It counts each read or write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:
- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:
- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:
- Attributability on page D5-2232.
- Meaningful ratios between common microarchitectural events on page D5-2265.

0x0010, BR_MIS_PRED, Mispredicted or not predicted branch Speculatively executed

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, ARM recommends that the counter counts all branches that are not taken.

0x0011, CPU_CYCLES, Cycle

The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a WFI or WFE instruction stops the clock. This means that it is CONSTRAINED UNPREDICTABLE whether or not CPU_CYCLES continues to increment when the clocks are stopped by WFI and WFE instructions.

Note

Unlike PMCCNTR, this count is not affected by PMCR.DP, PMCR.D, or PMCR.C:
- The counter is not incremented in prohibited regions, so is not affected by PMCR.DP.
- The counter increments on every cycle, regardless of the setting of PMCR.D.
• The counter is reset when event counters are reset by PMCR.P, never by PMCR.C.

In a multithreaded implementation, CPU_CYCLES counts each cycle for the processor for which this PE thread was active and could issue an instruction. For more information, see Cycle event counting on multithreaded implementations on page D5-2264.

0x0012, BR_PRED, Predictable branch Speculatively executed

The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. ARM recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by BR_MIS_PRED.

If no program-flow prediction resources are implemented, this event is optional, but ARM recommends that BR_PRED counts all branches.

0x0013, MEM_ACCESS, Data memory access

The counter counts Memory-read operations and Memory-write operations that the PE made. The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The counter does not increment as a result of:

• Instruction memory accesses, see Definition of terms on page D5-2240.
• Translation table walks.
• Cache maintenance instructions.
• Write-back from any cache.
• Refilling of any cache.

0x0014, L1I_CACHE, Attributable Level 1 instruction cache access

The counter counts Attributable instruction memory accesses that access at least the Level 1 instruction or unified cache. Each access to other Level 1 instruction memory structures, such as refill buffers, is also counted.

See also Attributability on page D5-2232.

0x0015, L1D_CACHE_WB, Attributable Level 1 data cache write-back

The counter counts every write-back of data from the Level 1 data or unified cache. The counter counts each write-back that causes data to be written from the Level 1 cache to outside of the Level 1 cache. For example, the counter counts the following cases:

• A write-back that causes data to be written to a Level 2 cache or memory.
• A write-back of a recently fetched cache line that has not been allocated to the Level 1 cache.
• Transfer of data from the Level 1 cache to outside of this cache made as a result of a coherency request. The conditions determining which of these are counted for transfers to other Level 1 caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

Whether write-backs made as a result of cache maintenance instructions are counted is IMPLEMENTATION DEFINED.

The counter does not count:

• The invalidation of a cache line without any write-back to a Level 2 cache or memory.
• Writes from the PE that write through the Level 1 cache to outside of the Level 1 cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See Attributability on page D5-2232.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation. See also Attributability on page D5-2232.

0x0016, L2D_CACHE, Attributable Level 2 data cache access

The counter counts Attributable Memory-read operations and Attributable Memory-write operations, that the PE made, that access at least the Level 2 data or unified cache. Each access to a cache line is counted including refills of and write-backs from the Level 1 data, instruction, or unified caches. Each access to other Level 2 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count:
• Operations made by other PEs that share this cache.
• Cache maintenance instructions.

See also Attributability on page D5-2232.

0x0017, L2D_CACHE_REFILL, Attributable Level 2 data cache refill

The counter counts Attributable Memory-read operations and Attributable Memory-write operations, that the PE made, that access at least the Level 2 data or unified cache and cause a refill of a Level 1 data, instruction, or unified cache or of the Level 2 data or unified cache. Each read from or write to the cache that causes a refill from outside the Level 1 and Level 2 caches is counted.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:
• Accesses to the Level 2 cache that cause a refill that is satisfied by another Level 2 cache, a Level 3 cache, or memory.
• Refills of and write-backs from any Level 1 data, instruction or unified cache that cause a refill from outside the Level 1 and Level 2 caches.
• Accesses to the Level 2 cache that cause a refill of a Level 1 cache from outside of the Level 1 and Level 2 caches, even if there is no refill of the Level 2 cache.

The counter does not count, as events on this PE:
• Accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.
• Accesses to the Level 2 cache that generate a memory access but not a new linefill, such as write-through writes that hit in the Level 2 cache.
• Accesses to the Level 2 cache that are part of a Level 1 cache refill or write-back that hit in the Level 2 cache so do not cause a refill from outside of the Level 1 and Level 2 caches.
• Operations made by other PEs that share this cache.
• Cache maintenance instructions.
• A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 and Level 2 caches, for example:
  — A write-back from a Level 1 cache to a Level 2 cache.
  — A write from a coalescing buffer of a full cache line.
  — A DC ZVA operation.
• A write that misses in the cache, and writes through the cache without allocating a line.
See also:

- **Attributability** on page D5-2232.
- **Meaningful ratios between common microarchitectural events** on page D5-2265.

**0x0018, L2D_CACHE_WB, Attributable Level 2 data cache write-back**

The counter counts every write-back of data from the Level 2 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 2 cache to outside the Level 1 and Level 2 caches. For example, the counter counts:

- A write-back that causes data to be written to a Level 3 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 2 cache.

Each write-back is counted once, even if it requires multiple accesses to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 2 cache to outside the Level 1 and Level 2 cache made as a result of a coherency request.
- Write-backs made as a result of Cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 3 cache or memory.
- Writes from the PE or Level 1 data or unified cache that write through the Level 2 cache to outside the Level 1 and Level 2 caches.
- Transfers of data from the Level 2 cache to a Level 1 cache, to satisfy a Level 1 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also **Attributability** on page D5-2232.

**0x0019, BUS_ACCESS, Attributable Bus access**

The counter counts Memory-read operations and Memory-write operations that access outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

The definition of a bus access is IMPLEMENTATION DEFINED but physically is a single beat rather than a burst. That is, for each bus cycle for which the bus is active.

Bus accesses include refills of and write-backs from data, instruction, and unified caches. Whether bus accesses include operations that do use the bus but not explicitly transfer data is IMPLEMENTATION DEFINED.

An Unattributable bus access occurs when a requestor outside the PE makes a request that results in a bus access, for example, a coherency request. If the bus is shared, then an Unattributable bus access is not counted. If the bus is not shared, then the event is counted.

If the bus is shared, then only Attributable bus accesses are counted. If the bus is not shared, then all bus accesses are counted.

Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

The maximum increment in any given cycle is implementation defined.

See also:

- **Attributability** on page D5-2232.
- **Meaningful ratios between common microarchitectural events** on page D5-2265.
0x001A, MEMORY_ERROR, Local memory error

The counter counts every occurrence of a memory error signaled by a memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

0x001B, INST_SPEC, Operation Speculatively executed

The counter counts instructions that are Speculatively executed by the PE. This includes instructions that are subsequently not architecturally executed. As a result, this event counts a larger number of instructions than the number of instructions architecturally executed. The definition of Speculatively executed is IMPLEMENTATION DEFINED.

0x001D, BUS_CYCLES, Bus cycle

The counter increments on every cycle of the interface at the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

Note

If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.

See also Meaningful ratios between common microarchitectural events on page D5-2265.

0x001F, L1D_CACHE_ALLOCATE, Attributable Level 1 data cache allocation without refill

The counter increments on every Attributable write that writes an entire line into the Level 1 cache without fetching from outside the Level 1 cache, for example:

• A write from a coalescing buffer of a full cache line.
• A DC ZVA operation.

See also Attributability on page D5-2232.

0x0020, L2D_CACHE_ALLOCATE, Attributable Level 2 data cache allocation without refill

The counter increments on every Attributable write that writes an entire line into the Level 2 cache without fetching from outside the Level 1 or Level 2 caches, for example:

• A write-back from a Level 1 to Level 2 cache.
• A write from a coalescing buffer of a full cache line.
• A DC ZVA operation.

See also Attributability on page D5-2232.

0x0022, BR_MIS_PRED_RETIRED, Instruction architecturally executed, mispredicted branch

The counter counts all instructions counted by BR_RETIRED that were not correctly predicted. If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

0x0023, STALL_FRONTEND, No operation issued due to the frontend

The counter counts every cycle counted by the CPU_CYCLES event on which no operation was issued because there are no operations available to issue for this PE from the frontend.

The division between frontend and backend is IMPLEMENTATION DEFINED. Frontend and backend events must count at the same point in the pipeline.

Note

• For a simplified pipeline model of Fetch → Decode → Issue → Execute → Retire, ARM recommends that the events are counted when instructions are dispatched from Decode to Issue.
• On a given cycle, both events might be counted if the backend is unable to accept any operations and there are no operations available to issue from the frontend.

For more information, see *Cycle event counting on multithreaded implementations on page D5-2264.*

0x0024, STALL_BACKEND, No operation issued due to the backend

The counter counts every cycle counted by the CPU_CYCLES event on which no operation was issued because either:
• The backend is unable to accept any of the operations available for issue for this PE.
• The backend is unable to accept any operations.

For example, the back end might be unable to accept operations because of a resource conflict or non-availability.

The division between frontend and backend is IMPLEMENTATION DEFINED. Frontend and backend events must count at the same point in the pipeline. See STALL_FRONTEND for more information.

For more information, see *Cycle event counting on multithreaded implementations on page D5-2264.*

0x0025, L1D_TLB, Attributable Level 1 data or unified TLB access

The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that causes a TLB access to at least the Level 1 data or unified TLB. Each access to a TLB record is counted including the multiple accesses of instructions, such as LDM or STM.

The counter does not count TLB maintenance instructions.

See also *Attributability on page D5-2232.*

0x0026, L1I_TLB, Attributable Level 1 instruction TLB access

The counter counts each Attributable Instruction memory access that causes a TLB access to at least the Level 1 instruction or unified TLB.

The counter does not count TLB maintenance instructions.

See also *Attributability on page D5-2232.*

0x0027, L2I_CACHE, Attributable Level 2 instruction cache access

The counter counts Attributable instruction memory accesses that access at least the Level 2 instruction or unified cache. Each Attributable access to other Level 2 instruction memory structures, such as refill buffers, is also counted.

See also *Attributability on page D5-2232.*

0x0028, L2I_CACHE_REFILL, Attributable Level 2 instruction cache refill

The counter counts Attributable instruction memory accesses that cause a refill of at least the Level 2 instruction or unified cache. This includes each Attributable memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

A refill includes any Attributable access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count cache maintenance instructions.

See also:
• *Attributability on page D5-2232.*
• *Meaningful ratios between common microarchitectural events on page D5-2265.*
0x0029, **L3D_CACHE_ALLOCATE**, Attributable Level 3 data cache allocation without refill

The counter increments on every Attributable write that writes an entire line into the Level 3 cache without fetching from outside the Level 1, Level 2, or Level 3 cache, for example:

- A write-back from a Level 2 to Level 3 cache.
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also **Attributability** on page D5-2232.

0x002A, **L3D_CACHE_REFILL**, Attributable Level 3 data cache refill

The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that the PE makes that accesses at least the Level 3 data or unified cache and causes a refill of a Level 1 or Level 2 instruction, data, or unified cache or of the Level 3 data or unified cache. Each read from or write to the cache that causes a refill from outside the Level 1, Level 2, and Level 3 caches is counted.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count as events on this PE:

- Accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.
- Accesses to the Level 3 cache that generate a memory access but not a new linefill, such as write-through writes that hit in the Level 3 cache.
- Accesses to the Level 3 cache that are part of a Level 1 or Level 2 cache refill or write-back that hit in the Level 3 cache so do not cause a refill from outside of the Level 1, Level 2, and Level 3 caches.
- Operations made by other PEs that share this cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1, Level 2, and Level 3 cache, for example:
  - A write-back from a Level 2 to Level 3 cache.
  - A write of a full cache line from a coalescing buffer.
  - A DC ZVA operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

See also:
- **Attributability** on page D5-2232.
- **Meaningful ratios between common microarchitectural events** on page D5-2265.

0x0028, **L3D_CACHE**, Attributable Level 3 data cache access

The counter counts Attributable Memory-read operations and Attributable Memory-write operations, that the PE made, that access at least the Level 3 data or unified cache. Each access to a cache line is counted including refills of and write-backs from the Level 1 or Level 2 data, instruction, or unified caches. Each access to other Level 3 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count:

- Operations made by other PEs that share the Level 3 data or unified cache.
- Cache maintenance instructions.

See also **Attributability** on page D5-2232.
0x002C, L3D_CACHE_WB, Attributable Level 3 data cache write-back

The counter counts every write-back of data from the Level 3 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 3 cache to outside of the Level 1, Level 2, and Level 3 caches. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 4 cache, or to memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 3 cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 3 cache to outside the Level 1, Level 2, and Level 3 caches made as a result of a coherency request.
- A write-back made as a result of a Cache maintenance instruction.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 4 cache or memory.
- Writes from the PE, Level 1, or Level 2 data or unified cache, that write through the Level 3 cache to outside of the Level 3 cache.
- Transfers of data from the Level 3 cache to a Level 1 or Level 2 cache, to satisfy a Level 1 or Level 2 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then Unattributable write-back events are not counted. If the cache is not shared, then Unattributable write-back events are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also Attributability on page D5-2232.

0x002D, L2D_TLB_REFILL, Attributable Level 2 data TLB refill

The counter counts each Attributable Memory-read operation or Attributable Memory-write operation that causes a TLB refill of at least the Level 2 data or unified TLB. It counts each Attributable read or Attributable write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- Attributability on page D5-2232.
- Meaningful ratios between common microarchitectural events on page D5-2265.

0x002E, L2I_TLB_REFILL, Attributable Level 2 instruction TLB refill

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 2 instruction TLB. This includes each Attributable Instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.
See also:
•  Attribution on page D5-2232.
•  Meaningful ratios between common microarchitectural events on page D5-2265.

0x002F, L2D_TLB, Attributable Level 2 data or unified TLB access
The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 data or unified TLB. Each access to a TLB record is counted, including the multiple accesses of instructions such as LDM or STM.
The counter does not count TLB maintenance instructions.
See also Attribution on page D5-2232.

0x0030, L2I_TLB, Attributable Level 2 instruction TLB access
The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 instruction or unified TLB.
The counter does not count TLB maintenance instructions.
See also Attribution on page D5-2232.

0x0031, REMOTE_ACCESS, Access to another socket in a multi-socket system
The counter counts each Attributable memory read operation or memory write operation that causes an access to another socket in a multi-socket system.
It is IMPLEMENTATION DEFINED whether an access that causes a snoop into another socket but does not return data from or pass data to the remote socket is counted.
See also Attribution on page D5-2232.

0x0032, LL_CACHE, Last Level cache access
The counter counts each Attributable memory read operation or write operation that causes a cache access to at least the Last Level data or unified cache. Cache maintenance instructions do not count as events.
See also Attribution on page D5-2232.

0x0033, LL_CACHE_MISS, Last Level cache miss
The Counter counts each Attributable Memory-read operation or Memory-write operation that causes a cache access to at least the Last Level data or unified cache, but is not completed by the Last Level cache. That is, either of the following:
• A memory read operation that does not return data from the Last Level cache.
• A memory write operation that does not update the Last Level cache.
The counter does not count operations that are completed by a cache above the Last Level cache. Cache maintenance instructions do not count as events.
See also:
•  Attribution on page D5-2232.
•  Meaningful ratios between common microarchitectural events on page D5-2265.

0x0034, DTLB_WALK, Access to data TLB causes a translation table walk
The counter counts each Attributable memory read or memory write operation that causes a refill of a data or unified TLB involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.
The counter does not count TLB maintenance instructions.
See also:
•  Attribution on page D5-2232.
•  Meaningful ratios between common microarchitectural events on page D5-2265.
0x0035, ITLB_WALK, Access to instruction TLB that causes a translation table walk

The counter counts each Attributable Instruction memory access that causes a refill of an instruction TLB, involving at least one translation table walk access. This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

The counter does not count TLB maintenance instructions.

See also:
• Attributability on page D5-2232.
• Meaningful ratios between common microarchitectural events on page D5-2265.

0x0036, LL_CACHE_RD, Last level cache access, read

As LL_CACHE, but counts only memory read operations.

Cache maintenance instructions do not count as events.

See also:
• Attributability on page D5-2232.
• Meaningful ratios between common microarchitectural events on page D5-2265.

0x0037, LL_CACHE_MISS_RD, Last level cache miss, read

As LL_CACHE_MISS, but counts only memory read operations.

Cache maintenance instructions do not count as events.

See also:
• Attributability on page D5-2232.
• Meaningful ratios between common microarchitectural events on page D5-2265.

0x0038, REMOTE_ACCESS_RD, Access to another socket in a multi-socket system, read

As REMOTE_ACCESS, but counts only memory read operations.

See also:
• Attributability on page D5-2232.
• Meaningful ratios between common microarchitectural events on page D5-2265.

D5.10.4 Statistical Profiling Extension microarchitectural events

The event numbers of the Statistical Profiling Extension microarchitectural events are reserved for the specified events. If the Statistical Profiling Extension is implemented these events must be implemented.

Table D5-9 lists the PMU microarchitectural event numbers required by the Statistical Profiling Extension event number order.

Note
As Table D5-9 shows, event numbers for Statistical Profiling microarchitectural events are allocated from a single range of event numbers. Table D5-7 on page D5-2244 shows the unallocated numbers from this range.

<table>
<thead>
<tr>
<th>Event number</th>
<th>Event type</th>
<th>Event mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x4000</td>
<td>Microarchitectural</td>
<td>SAMPLE_POP</td>
<td>Sample Population</td>
</tr>
<tr>
<td>0x4001</td>
<td>Microarchitectural</td>
<td>SAMPLE_FEED</td>
<td>Sample Taken</td>
</tr>
<tr>
<td>0x4002</td>
<td>Microarchitectural</td>
<td>SAMPLE_FILTRATE</td>
<td>Sample Taken and not removed by filtering</td>
</tr>
<tr>
<td>0x4003</td>
<td>Microarchitectural</td>
<td>SAMPLE_COLLISION</td>
<td>Sample collided with previous sample</td>
</tr>
</tbody>
</table>
The events corresponding to the Statistical Profiling Extension microarchitectural event numbers are:

0x4000, SAMPLE_POP, Sample Population
The counter increments for each operation that might be sampled, whether or not the operation was sampled. Operations that are executed at an Exception level or Security state in which the Statistical Profiling Extension is disabled are not counted.

0x4001, SAMPLE_FEED, Sample Taken
The counter increments each time the sample interval counter reaches zero and is reloaded, and the sample does not collide with the a previous sample. Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x4002, SAMPLE_FILTRATE, Sample taken and not removed by filtering
The counter increments each time that a completed sample record is checked against the filters and not removed. Sample records that are not removed by filtering, but are discarded before being written to the Profiling Buffer because of a Profiling Buffer management event, are counted.

0x4003, SAMPLE_COLLISION, Sample collided with a previous sample
The counter increments for each sample record that is taken when the previous sampled operation has not completed generating its sample record.

Note
These events are discoverable through a read of PMCEID0_EL0[35:32] in AArch64 state.

Meaningful ratios between Statistical Profiling Extension PMU microarchitectural events

The architecture highlights some meaningful ratios that can be derived from the common microarchitectural events. Table D5-10 lists the ratios.

<table>
<thead>
<tr>
<th>Numerator</th>
<th>Denominator</th>
<th>Ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x4001 SAMPLE_FEED</td>
<td>0x4000 SAMPLE_POP</td>
<td>Attributable sampling ratio</td>
</tr>
<tr>
<td>0x4002 SAMPLE_FILTRATE</td>
<td>0x4001, SAMPLE_FEED</td>
<td>Attributable ratio of samples that met the filtering criteria</td>
</tr>
</tbody>
</table>

Note
The number of operations that are sampled is counted by SAMPLE_FEED meaning that if all filtering is disabled then SAMPLE_FILTRATE counts the same as SAMPLE_FEED.

For more information see Chapter D6 The Statistical Profiling Extension.

D5.10.5 Cycle event counting on multithreaded implementations

For most events, the event is only counted when it is attributable to the counting PE or thread, see Attributability on page D5-2232.

Multithreaded implementations can have various forms, some examples of these are:

- **Simultaneous Multithreading** (SMT), where every PE thread is active on every cycle.
- **Fine-grained Multithreading** (FGMT), also known as a Barrel processor, where one PE thread is active on each cycle, and this changes regularly.
Switch on Event Multithreading (SoEMT), also known as Coarse-grained Multithreading (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

When the PMEVTYPER<n>_EL0.MT bit is set to 0, the CPU_CYCLES event only counts cycles on which the thread was active. For the example multithreaded implementations, this means that:

- For an SMT implementation, the CPU_CYCLES event counts every cycle.
- For a particular FGMT implementation, that alternates between two threads on each cycle, the CPU_CYCLES event counts every other cycle.
- For a particular SoEMT implementation, that is waiting for a long latency operation, the CPU_CYCLES event does not count cycles, as the PE thread is not active.

If the PMEVTYPER<n>_EL0.MT bit is set to 1, the processor counts each cycle, and can only count a maximum of one cycle each cycle.

In addition, the STALL_FRONTEND and STALL_BACKEND events only count cycles that are counted by the CPU_CYCLES event, and so have the same limitation. For example, in an SMT implementation, if a PE thread cannot issue an instruction because of contention with other PE threads, these are counted as STALL_BACKEND cycles.

If the PMEVTYPER<n>_EL0.MT bit is set to 1, the PE only counts cycles on which no operation is issued from any thread.

Note

The PMCCNTR register counts every processor cycle.

### D5.10.6 Meaningful ratios between common microarchitectural events

The architecture highlights some meaningful ratios that can be derived from the common microarchitectural events. Table D5-11 lists the highlighted ratios.

<table>
<thead>
<tr>
<th>Numerator</th>
<th>Denominator</th>
<th>Ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0001</td>

</tbody>
</table>
D5.10.7 Required events

PMUv3 requires that an implementation includes the following common events:

- **0x0000, SW_INCR**, Instruction architecturally executed, Condition code check pass, software increment.
- **0x0003, L1D_CACHE_REFILL**, Attributable Level 1 data cache refill.
  
  **Note**: Event 0x0003 is only required if the implementation includes a Level 1 data or unified cache.

- **0x0004, L1D_CACHE**, Attributable Level 1 data cache access.
  
  **Note**: Event 0x0004 is only required if the implementation includes a Level 1 data or unified cache.

- **0x0010, BR_MIS_PRED**, Mispredicted or not predicted branch Speculatively executed.
  
  **Note**: Event 0x0010 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in Common microarchitectural events on page D5-2252.

- **0x0011, CPU_CYCLES**, Cycle.
- **0x0012, BR_PRED**, Predictable branch Speculatively executed.
  
  **Note**: Event 0x0012 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in Common microarchitectural events on page D5-2252.

- At least one of:
  - **0x0008, INST_RETIRED**, Instruction architecturally executed.
  - **0x001B, INST_SPEC**, Operation Speculatively executed.

  **Note**: ARM strongly recommends that event 0x008 is implemented.

- When ARMv8.1-PMU is implemented:
  - **0x0023, STALL_FRONTEND**, No operation issued due to the frontend.
  - **0x0024, STALL_BACKEND**, No operation issued due to the backend.

D5.10.8 IMPLEMENTATION DEFINED event numbers

For IMPLEMENTATION DEFINED event numbers, each counter is defined, independently, to either:

- Increment only once for each event.
- Count the duration for which an event occurs.
ARM recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common count numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, ARM recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

ARM strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINE events:

- Cumulative duration of stalls resulting from the holes in the instruction availability, separating out counts for key buffering points that might exist.
- Cumulative duration of data-dependent stalls, separating out counts for key dependency classes that might exist.
- Cumulative duration of stalls due to unavailability of execution resources, including, for example, write buffers, separating out counts for key resources that might exist.
- Missed superscalar issue opportunities, if relevant, separating out counts for key classes of issue that might exist.
- Miss rates for different levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a PSTATE.\{A, I, F\} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist.

An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.

- Any other microarchitectural features that the implementer considers are valuable to count.

The IMPLEMENTATION DEFINED event numbers are 0x040 to 0x3FF. Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events lists the ARM recommended standardized numbering scheme for these events.
D5.11 Performance Monitors Extension registers

The following section describes the Performance Monitors Extension registers.

The following subsections give general information about the Performance Monitors Extension registers, that apply for both Execution states:

- Relationship between AArch32 and AArch64 Performance Monitors registers.
- Access permissions.

Performance monitors registers on page K13-6610 summarizes the Performance Monitors Extension registers in AArch64 state.

Performance monitors registers on page K13-6629 summarizes the Performance Monitors Extension registers in AArch32 state.

D5.11.1 Relationship between AArch32 and AArch64 Performance Monitors registers

Table K13-2 on page K13-6594 lists the Performance Monitors register names for AArch32 and AArch64 states.

D5.11.2 Access permissions

Each Exception level is able to control Performance Monitors System register accesses at lower Exception levels. The access control flow is:

1. At EL0:
   - Writes to PMUSERENR are UNDEFINED.
   - Reads and writes of PMINTENSET and PMINTENCLR are UNDEFINED.
   - If PMUSERENR.EN == 0:
     - If PMUSERENR.SW == 0 then writes to PMSWINC are trapped to EL1.
     - If PMUSERENR.CR == 0 then reads of PMCCNTR are trapped to EL1.
     - If PMUSERENR.ER == 0 then reads of PMEVCNTR<><> and PMXEVCNTR, and reads and writes of PMSELR, are trapped to EL1.
     - Otherwise, for all other Performance Monitors registers, other than reads of PMUSERENR, reads and writes are trapped to EL1.

   **Note**
   If HCR.TGE==1, then all exceptions that would be taken to EL1 are instead taken to EL2.

2. Otherwise, at EL1 and EL0 in Non-secure state, if EL2 is implemented:
   - If HDCR.TPME == 1 then accesses to PMCR are trapped to EL2.
   - If HDCR.TPM == 1 then accesses to all Performance Monitors registers, including PMCR, are trapped to EL2.

3. Otherwise, at EL2, EL1 and EL0, if EL3 is implemented and using AArch64, and if MDCR_EL3.TPM == 1 then accesses to all Performance Monitors registers are trapped to EL3.

   **Note**
   These traps are not possible if EL3 is using AArch32.

4. Otherwise, the access is permitted.

   **Note**
   These traps and enables only apply to System register accesses using System register access instructions. For accesses through the optional memory-mapped or external debug interfaces, see Access permissions for external views of the Performance Monitors on page 13-6007.
For details of the headings used in Table D5-12, see Configurable instruction enables and disables, and trap controls on page D1-1910. In addition, the following terms are used:

**Instruction**
This shows the access instruction, read (\textit{MRS}), write (\textit{MSR}), or both (-). In AArch32 state, the equivalent instructions are \textit{MRC} and \textit{MCR}.

**Default access**
If the Default access is - then the access is trapped from EL0 to EL1 unless the PMUSERENR enables are set to 1.

**Resultant access permission**
This indicates the resulting access permission provided the enables at EL0 are enabled and the traps to EL2 or EL3 are disabled.

Table D5-12 shows the access permissions for System register accesses to the Performance Monitors registers.

Chapter D6
The Statistical Profiling Extension

This chapter describes the Statistical Profiling Extension. It contains the following sections:

- Statistical Profiling on page D6-2272.
- Programmers' Model on page D6-2280.
- Enable and Filtering controls on page D6-2283.
- Profiling Buffer management interrupt on page D6-2289.
D6.1 Statistical Profiling

Statistical profiling is a four stage process.
1. An operation is chosen from a sample population, at a programmable interval that might have some random, or pseudorandom, perturbation.
2. A trace of the sampled operation is taken. This includes the PC, events, timings, and data addresses, related to the sampled operation. This is the profiling operation.
3. Before a sample record is created, it is possible to filter out potential sample records generated by the profiling operation by reference to, any or all of the following:
   a. The type of operation.
   b. The Exception level.
   c. Event and latency.
4. A sample record is created that contains the traced information. Sample records that meet the criteria of the filter are written to and stored in a memory buffer. These sample records can be processed by software when the memory buffer is full.

D6.1.1 ARMv8.2 Statistical Profiling Extension

This section gives an overview of the Statistical Profiling Extension.

Non-invasive behavior

Statistical Profiling is a non-invasive debug operation:
• While profiling is enabled, the operation and performance of the processing element (PE) must not be significantly impacted between sampled operations, that is, other than for writing out sample records and processing Profiling Buffer management interrupts.
• The performance of the sampled operation and the performance of the PE in general must not be significantly impacted. The sample records are not written to memory until after the sampled operation has completed. However, this does not apply when the user selects a collection of physical addresses for data access operations. In this case, the impact is IMPLEMENTATION DEFINED.
• The profiling operation to write sample records must not be excessively impactful on the performance of the sampled operation or the performance of the PE generally.

Defining the sample population

All samples are taken from a population of operations. The population is dynamic rather than static. That is, if a program executes the same operation multiple times (for example, because of loops and subroutines) then that operation appears multiple times in the population.

The operations are an IMPLEMENTATION DEFINED choice between:
• Architecture instructions.
• IMPLEMENTATION DEFINED microarchitectural operations (micro-ops).

Architecture instruction means a single instruction that is defined by the ARMv8 instruction set architecture in AArch64 state.

An architecture instruction might create one or more micro-ops at any point in the execution pipeline. The definition of a micro-op is implementation specific. An architecture instruction might create more than one micro-op for each instruction. A micro-op might also be removed or merged with another micro-op in the execution stream, so an architecture instruction might create no micro-ops for an instruction.

Any arbitrary translation of architecture instructions to an equivalent sequence of micro-ops is permitted. In some implementations, the relationship between architecture instructions and micro-ops might vary over time.

Note

Sampling from architecture instructions does not require that the instruction is architecturally executed.
**Operation sampling**

A sample operation is as follows:

1. A sampling interval is written to a sample interval counter by software. The interval is measured in operations.
2. The sample interval counter is decremented by hardware for each operation when sampling is enabled.
3. When the sample interval counter reaches zero, then:
   a. If random perturbation is enabled, the PE continues to count for a random number of further operations while sampling is enabled.
   b. An operation is chosen for profiling.

   **Note**
   The choice of operation around the sampling point is arbitrary. The chosen operation might be the operation for which the sample interval counter reached 0, or the next operation. The choice must be applied consistently so as not to introduce sampling bias.

4. The sample interval counter is reloaded and the process loops to step 2. It is IMPLEMENTATION DEFINED whether the sample interval counter is reloaded before step 3.a) or at step 3.b). That is, before or after counting the random number of further operations. See Controlling when an operation is sampled on page D6-2280.
5. The chosen operation is marked as the sampled operation. The PE collects information about the sampled operation as it executes by a profiling operation.
6. When the sampled operation is completed, the sample record is captured.

The sampled lifespan of an operation:

- Starts with the decoded architectural instruction or micro-op is dispatched for issue.
- Completes when one of:
  — The instruction or micro-op is committed to the architectural state of the PE (including completion by generating a synchronous exception).
  — The speculative instruction or micro-op is discarded because of misspeculation. For more information see Misspeculation and non-architectural operations on page D6-2278.
  — The instruction or micro-op is replayed, on some microarchitectures. For more information see Non-architectural exceptions on page D6-2279.

**Random number generation**

The random number generator is IMPLEMENTATION DEFINED. Implementations might use a pseudorandom number. The random number generator must be reset into a useable state. An implementation might include IMPLEMENTATION DEFINED registers to further configure the random number generator.

It is IMPLEMENTATION DEFINED whether the PE adds the random number to the sample interval counter prior to counting down the interval, or after the counter reaches zero and the counter has been reloaded.

**Defining where operations are sampled**

The exact point in the sampled lifetime of operations at which sampled operations are chosen for profiling is IMPLEMENTATION DEFINED.

**Note**
ARM recommends that the point at which operations are sampled is linked to the definition of the Performance Monitoring Extension (PMU) STALL_FRONTEND and STALL_BACKEND events, so that sampling records information for STALL_BACKEND stalls.
Sample collisions

The maximum number of sampled operations that a PE can support simultaneously in flight is IMPLEMENTATION DEFINED. If the maximum number of sampled operations is in flight at the point when a new sample operation must be taken, the new sample is said to have collided with a previous sampled operation.

The PE records the fact that a sampled operation has collided with another sampled operation. Software can also count the number of collisions and gauge the impact of the collisions.

See Sample collision behavior on page D6-2281.

Operations that might be excluded from the sample population

It is IMPLEMENTATION DEFINED whether each of the following operations is part of the sample population:

- Operations on misspeculated paths.
- Operations (specifically micro-ops) that do not relate to any architecture instruction.
- Operations that generate non-architectural exceptions.

If the operation is not part of the sample population, the operation does not cause the sample interval counter to decrement, is not counted by the SAMPLE_POP event and therefore is never sampled.

If the operation is part of the sample population, the operation causes the sample interval counter to decrement, is counted by the SAMPLE_POP event, and might be sampled and counted by the SAMPLE_FEED event.

See also Misspeculation and non-architectural operations on page D6-2278.

D6.1.2 Collected data

Unless otherwise stated all sample records that are generated by a profiling operation contain:

- A timestamp, if enabled. This is one of:
  - CNTPCT_EL0.
  - CNTVCT_EL0.
  It is IMPLEMENTATION DEFINED how this timestamp relates to the sampled operation. It might be the time when the sampled operation was taken or any later time during the lifetime of the sampled operation, that is, up to the time when the sampled operation is completed.
  If the Generic Timer system counter is disabled and timestamps are enabled, then it is IMPLEMENTATION DEFINED whether:
    - The Statistical Profiling Extension behaves as if timestamps are disabled.
    - The timestamp that is collected in the sample record is UNKNOWN.

  Note
  This behavior describes when CNTEN,EN is cleared to 0. This behavior does not apply when the Generic Timer system counter is enabled but not accessible at the current Exception level.

- The context, if enabled, which is one or more of:
  - CONTEXTIDR_EL1.
  - CONTEXTIDR_EL2.
  - The Exception level.
  - The Security state.

- Information about whether the sampled operation generated an exception:
  - The target address for an exception generating operation is not collected.

- Information about whether the sampled operation completed execution.

If the sampled operation completes execution and does not generate an exception, the sample record also contains:

- The PC virtual address for the sampled operation.
- Information about whether the sampled operation is a branch, a load, a load atomic, a store, or other.
- Information about whether the sampled operation is conditional, conditional select, or not.
- The total latency, a cycle count of the lifetime of the sampled operation.
• The issue latency, a cycle count from the start of the lifetime of the sampled operation up to the point when the sampled operation starts executing. A sampled operation might be delayed, for example because the input operands were not available.

If the sampled operation does not complete execution or generates an exception it is UNPREDICTABLE whether the record contains all or any of this information and the other information about the operation listed in this section and the following subsections.

Where an operation generates an exception and the type of exception means a particular item is not computed by the operation, that information is not collected and written to a sample record.

The architecture defines a set of additional data that is collected in the sample record for each sampled operation. This is described in the following subsections, and comprises:
• Events.
• Cycle counters. Cycle count values as described in this architecture, which, for a particular implementation, are fixed with an IMPLEMENTATION DEFINED value, might be omitted from the sample record.
• Addresses.

In addition, the architecture permits IMPLEMENTATION DEFINED events, counters, and addresses to be collected.

### Additional information for each profiled branch or exception return

For a completed branch or exception return sampled operation, the profiling operation must record:
• The sampled operation type as an unconditional branch or a conditional branch. Sampled exception returns are treated as unconditional branches by the Statistical Profiling Extension.
• The target virtual address of the branch. The target virtual address includes the Exception level and Security state of the target.

--- **Note** ---

If the sampled operation is an illegal exception return, it is IMPLEMENTATION DEFINED whether the context information recorded in the target virtual address is the actual target context, or the target context that is described by the SPSR.

--- **Note** ---

• If the PE implements branch prediction, whether the branch was correctly predicted or mispredicted.
• Whether the branch was taken or not taken.
• Whether the branch was direct or indirect.

See also *Additional information for each profiled branch or exception return*.

--- **Note** ---

A sampled operation that generates an exception is not treated as a branch.

--- **Note** ---

### Additional information for each profiled memory access operation

For a completed load, store, or atomic sampled operation that does not generate an exception, the profiling operation must record:
• The data virtual and, if enabled, physical addresses being accessed.
  — If the applicable Top Byte Ignore (TBI) bit is set to one, the virtual address includes any top-byte tag.
  — The physical address is the address the PE accesses in the physical address space, and so includes the Secure Address Space Identifier.
• The sampled operation type, which includes:
  — Whether the sampled operation is a load, store, or atomic.
  — Whether the sampled operation is Load-Exclusive, Store-Exclusive or Load-acquire, Store-release.
  — Whether the sampled operation accesses the general-purpose or SIMD&FP registers.
• The translation latency, a cycle count from the virtual address being generated to the physical address being returned by the MMU.
• Whether the sampled operation accessed the Level 1 data cache and resulted in a hit.
• Whether the sampled operation accessed the data TLB and resulted in a hit.
• An optional, IMPLEMENTATION DEFINED, record of whether the sampled operation accessed Last Level data cache and resulted in a hit.
• An optional, IMPLEMENTATION DEFINED, record of whether the sampled operation accessed another socket in a multi-socket system.
• An optional, IMPLEMENTATION DEFINED, indicator of the data source for a load.

For each of the Last level cache and another socket indicators, it is IMPLEMENTATION DEFINED whether this information is present only for load accesses, only for store accesses, for neither, or for both.

--- Note ---
A store might be marked as not accessing a cache or another socket because it completed before doing so. For example, the write was held in a write buffer. This behavior is IMPLEMENTATION DEFINED, and such events must be interpreted with care.

---

If architecture instructions are sampled, then, for a sampled load/store operation that is not single-copy atomic, the data addresses are the lowest address that is accessed by the sampled operation.

Otherwise the information is for the micro-op that is sampled.

**Example D6-1 Sampling of micro-ops**

If an architectural load instruction is split into an address generation micro-op and a load micro-op, then when generating the sample record and filtering based on operation type:
• If the address generation micro-op is sampled, the sampled operation is treated as other.
• If the load micro-op is sampled, the sampled operation is treated as a load.

---

For more information see [Filtering sample records on page D6-2284](#) and [Operation Type packet on page D7-2315](#).

**Additional information for each profiled conditional instruction (including conditional branches)**

For a completed conditional branch, conditional select, conditional move, or conditional increment sampled operation, the profiling operation must record:
• That the sampled operation was conditional.
• Whether the condition passed or failed.

If a conditional instruction fails its condition code test, it is IMPLEMENTATION DEFINED whether any of the information for the sampled operation that is generated by executing the sampled operation is recorded. Any value that is recorded and is the result of executing the sampled operation is UNKNOWN.

**Example D6-2 Conditional branches**

A conditional branch operation fails its condition code test. It is IMPLEMENTATION DEFINED whether the sample record contains a branch target Address packet. If the sample record contains a branch target Address packet, the value in the packet is UNKNOWN.

**Additional information for other operations**

For cache maintenance operations by virtual address, cache prefetch, or address translation instructions, the profiling operation:
• Captures an IMPLEMENTATION DEFINED subset of the information captured for a load instruction.
• Treats the operation type as other when generating the sample record and filtering based on operation type.
See *Filtering sample records* on page D6-2284 and *Operation Type packet*.
