COMP9444 18s2 Variations on Backprop

Probability (3.1)

Begin with a set Ω – the sample space (e.g. 6 possible rolls of a die)

 $\omega \in \Omega$ is a sample point/possible world/atomic event

A probability space or probability model is a sample space with an assignment $P(\omega)$ for every $\omega \in \Omega$ s.t.

$$0 \le P(\omega) \le 1$$

$$\sum_{\omega} P(\omega) = 1$$

e.g.
$$P(1) = P(2) = P(3) = P(4) = P(5) = P(6) = \frac{1}{6}$$
.

An event A is any subset of Ω

$$P(A) = \sum_{\{\omega \in A\}} P(\omega)$$

e.g.
$$P(\text{die roll} < 4) = P(1) + P(2) + P(3) = \frac{1}{6} + \frac{1}{6} + \frac{1}{6} = \frac{1}{2}$$

COMP9444 18s2

Variations on Backprop

Outline

- Probability (3.1-3.6, 3.9.3, 3.10)
- Cross Entropy (5.5)
- Bayes' Rule (3.11)
- Weight Decay (5.2.2)
- Momentum (8.3)

COMP9444 18s2

2

Variations on Backprop

Random Variables (3.2)

A random variable (r.v.) is a function from sample points to some range (e.g. the Reals or Booleans)

For example, Odd(3) = true.

P induces a probability distribution for any r.v. X:

$$P(X = x_i) = \sum_{\{\omega: X(\omega) = x_i\}} P(\omega)$$

e.g.,
$$P(\text{Odd} = \text{true}) = P(1) + P(3) + P(5) = \frac{1}{6} + \frac{1}{6} + \frac{1}{6} = \frac{1}{2}$$

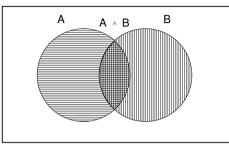

3

Probability and Logic

Logically related events must have related probabilities

For example, $P(a \lor b) = P(a) + P(b) - P(a \land b)$

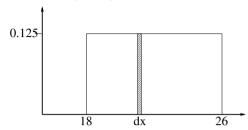

True

COMP9444 © Alan Blair, 2017-18

Probability for Continuous Variables

e.g. P(X = x) = U[18, 26](x) = uniform density between 18 and 26

Here *P* is a density; integrates to 1.

P(X = 20.5) = 0.125 really means

$$\lim_{dx\to 0} P(20.5 \le X \le 20.5 + dx)/dx = 0.125$$

7

Gaussian Distribution (3.9.3)

$$P(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-\mu)^2/2\sigma^2}$$

Variations on Backprop

- Cross Entropy
 - ▶ problem: least squares error function unsuitable for classification, where target = 0 or 1
 - ▶ mathematical theory: maximum likelihood
 - ▶ solution: replace with cross entropy error function
- Weight Decay
 - ▶ problem: weights "blow up", and inhibit further learning
 - ▶ mathematical theory: Bayes' rule
 - > solution: add weight decay term to error function
- Momentum
 - ▶ problem: weights oscillate in a "rain gutter"
 - > solution: weighted average of gradient over time

COMP9444 18s2

10

11

Cross Entropy

For classification tasks, target t is either 0 or 1, so better to use

$$E = -t \log(z) - (1 - t) \log(1 - z)$$

Variations on Backprop

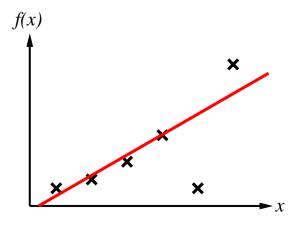

This can be justified mathematically, and works well in practice – especially when negative examples vastly outweigh positive ones. It also makes the backprop computations simpler

$$\frac{\partial E}{\partial z} = \frac{z - t}{z(1 - z)}$$
if $z = \frac{1}{1 + e^{-s}}$,
$$\frac{\partial E}{\partial s} = \frac{\partial E}{\partial z} \frac{\partial z}{\partial s} = z - t$$

Variations on Backprop

Least Squares Line Fitting

Maximum Likelihood (5.5)

H is a class of hypotheses

P(D|h) = probability of data D being generated under hypothesis $h \in H$. $\log P(D|h)$ is called the likelihood.

ML Principle: Choose $h \in H$ which maximizes the likelihood, i.e. maximizes P(D|h)[or, maximizes $\log P(D|h)$]

COMP9444 © Alan Blair, 2017-18

COMP9444 18s2 Variations on Backprop

Derivation of Least Squares

Suppose data generated by a linear function h, plus Gaussian noise with standard deviation σ .

$$P(D|h) = \prod_{i=1}^{m} \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2}(d_i - h(x_i))^2}$$

$$\log P(D|h) = \sum_{i=1}^{m} -\frac{1}{2\sigma^2}(d_i - h(x_i))^2 - \log(\sigma) - \frac{1}{2}\log(2\pi)$$

$$h_{ML} = \operatorname{argmax}_{h \in H} \log P(D|h)$$

$$= \operatorname{argmin}_{h \in H} \sum_{i=1}^{m} (d_i - h(x_i))^2$$

(Note: we do not need to know σ)

COMP9444

13

Derivation of Cross Entropy

For classification tasks, d is either 0 or 1.

Assume D generated by hypothesis h as follows:

$$P(1|h(x_i)) = h(x_i)$$
 $P(0|h(x_i)) = (1-h(x_i))$ i.e. $P(d_i|h(x_i)) = h(x_i)^{d_i}(1-h(x_i))^{1-d_i}$

then

$$\log P(D|h) = \sum_{i=1}^{m} d_i \log h(x_i) + (1 - d_i) \log(1 - h(x_i))$$

$$h_{ML} = \operatorname{argmax}_{h \in H} \sum_{i=1}^{m} d_i \log h(x_i) + (1 - d_i) \log(1 - h(x_i))$$

(Can be generalized to multiple classes.)

15

Inference by Enumeration

Start with the joint distribution:

	toothache		¬ toothache	
	catch	¬ catch	catch	¬ catch
cavity	.108	.012	.072	.008
¬ cavity	.016	.064	.144	.576

For any proposition ϕ , sum the atomic events where it is true:

$$P(\phi) = \sum_{\omega:\omega \models \phi} P(\omega)$$

$$P(toothache) = 0.108 + 0.012 + 0.016 + 0.064 = 0.2$$

Joint Probability Distribution

We assume there is some underlying joint probability distribution over the three random variables Toothache, Cavity and Catch, which we can write in the form of a table:

	toothache		¬ toothache	
	catch	¬ catch	catch	¬ catch
cavity	.108	.012	.072	.008
¬ cavity	.016	.064	.144	.576

Note that the sum of the entries in the table is 1.0.

For any proposition ϕ , sum the atomic events where it is true:

$$P(\phi) = \sum_{\omega:\omega \models \phi} P(\omega)$$

COMP9444

Inference by Enumeration

	toothache		¬ toothache	
	catch	¬ catch	catch	¬ catch
cavity	.108	.012	.072	.008
¬ cavity	.016	.064	.144	.576

For any proposition ϕ , sum the atomic events where it is true:

$$P(\phi) = \sum_{\omega:\omega \models \phi} P(\omega)$$

 $P(\text{cavity} \lor \text{toothache})$

$$= 0.108 + 0.012 + 0.072 + 0.008 + 0.016 + 0.064 = 0.28$$

16

Conditional Probability (3.5-3.6)

If we consider two random variables a and b, with $P(b) \neq 0$, then the conditional probability of a given b is

$$P(a|b) = \frac{P(a \land b)}{P(b)}$$

Variations on Backprop

Alternative formulation: $P(a \land b) = P(a|b)P(b) = P(b|a)P(a)$

When we consider a sequence of random variables at successive time steps, they can be chained together using this formula repeatedly:

$$P(X_{n},...,X_{1}) = P(X_{n}|X_{n-1},...,X_{1})P(X_{n-1},...,X_{1})$$

$$= P(X_{n}|X_{n-1},...,X_{1})P(X_{n-1}|X_{n-2},...,X_{1})$$

$$= ... = \prod_{i=1}^{n} P(X_{i}|X_{i-1},...,X_{1})$$

© Alan Blair, 2017-18 COMP9444

Conditional Probability by Enumeration

	toothache		¬ toothache	
	catch	¬ catch	catch	¬ catch
cavity	.108	.012	.072	.008
¬ cavity	.016	.064	.144	.576

$$P(\neg \texttt{cavity} | \texttt{toothache}) = \frac{P(\neg \texttt{cavity} \land \texttt{toothache})}{P(\texttt{toothache})}$$
$$= \frac{0.016 + 0.064}{0.108 + 0.012 + 0.016 + 0.064} = 0.4$$

Variations on Backprop

19

Bayes' Rule (3.11)

The formula for conditional probability can be manipulated to find a relationship when the two variables are swapped:

$$P(a \wedge b) = P(a \mid b)P(b) = P(b \mid a)P(a)$$

$$\rightarrow$$
 Bayes' rule $P(a|b) = \frac{P(b|a)P(a)}{P(b)}$

This is often useful for assessing the probability of an underlying cause after an effect has been observed:

$$P(\text{Cause}|\text{Effect}) = \frac{P(\text{Effect}|\text{Cause})P(\text{Cause})}{P(\text{Effect})}$$

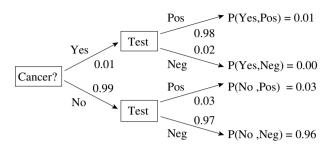

Example: Medical Diagnosis

Question: Suppose we have a test for a type of cancer which occurs in 1% of patients. The test has a sensitivity of 98% and a specificity of 97%. If a patient tests positive, what is the probability that they have the cancer?

Answer: There are two random variables: Cancer (true or false) and Test (positive or negative). The probability is called a prior, because it represents our estimate of the probability before we have done the test (or made some other observation). The sensitivity and specificity are interpreted as follows:

$$P(positive | cancer) = 0.98$$
, and $P(positive | \neg cancer) = 0.97$

Bayes' Rule

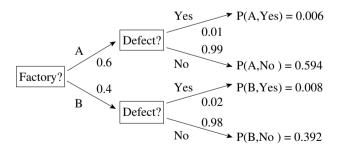

$$\begin{array}{lcl} P({\tt cancer} \, | \, {\tt positive}) & = & \frac{P({\tt positive} \, | \, {\tt cancer}) P({\tt cancer})}{P({\tt positive})} \\ & = & \frac{0.98*0.01}{0.98*0.01 + 0.03*0.99} = \frac{0.01}{0.01 + 0.03} = \frac{1}{4} \end{array}$$

COMP9444 © Alan Blair, 2017-18

COMP9444 18s2 Variations on Backprop 22 COMP9444 18s2 Variations on Backprop 23

Bayes' Rule

$$\begin{split} P(\texttt{A}|\texttt{defect}) &= \frac{P(\texttt{defect}|\texttt{A})P(\texttt{A})}{P(\texttt{defect})} \\ &= \frac{0.01*0.6}{0.01*0.6+0.02*0.4} = \frac{0.006}{0.006+0.008} = \frac{3}{7} \end{split}$$

Example: Light Bulb Defects

Question: You work for a lighting company which manufactures 60% of its light bulbs in Factory A and 40% in Factory B. One percent of the light bulbs from Factory A are defective, while two percent of those from Factory B are defective. If a random light bulb turns out to be defective, what is the probability that it was manufactured in Factory A?

Answer: There are two random variables: Factory (A or B) and Defect (Yes or No). In this case, the prior is:

$$P(A) = 0.6, \qquad P(B) = 0.4$$

The conditional probabilities are:

$$P(\text{defect} \mid A) = 0.01$$
, and $P(\text{defect} \mid B) = 0.02$

COMP9444 © Alan Blair, 2017-18

Bayes Rule in Machine Learning

H is a class of hypotheses

P(D|h) = probability of data D being generated under hypothesis $h \in H$.

P(h|D) = probability that h is correct, given that data D were observed.

Bayes' Theorem:

$$P(h|D)P(D) = P(D|h)P(h)$$

$$P(h|D) = \frac{P(D|h)P(h)}{P(D)}$$

P(h) is called the prior.

COMP9444 © Alan Blair, 2017-18

© Alan Blair, 2017-18

21

Weight Decay (5.2.2)

Assume that small weights are more likely to occur than large weights, i.e.

$$P(w) = \frac{1}{Z}e^{-\frac{\lambda}{2}\sum_{j}w_{j}^{2}}$$

where Z is a normalizing constant. Then the cost function becomes:

$$E = \frac{1}{2} \sum_{i} (z_i - t_i)^2 + \frac{\lambda}{2} \sum_{i} w_j^2$$

This can prevent the weights from "saturating" to very high values.

Problem: need to determine λ from experience, or empirically.

COMP9444 © Alan Blair, 2017-18

COMP9444 18s2

Variations on Backprop

26

Conjugate Gradients

Compute matrix of second derivatives $\frac{\partial^2 E}{\partial w_i \partial w_j}$ (called the Hessian).

Approximate the landscape with a quadratic function (paraboloid).

Jump to the minimum of this quadratic function.

Natural Gradients (Amari, 1995)

Use methods from information geometry to find a "natural" re-scaling of the partial derivatives.

COMP9444 © Alan Blair, 2017-18

COMP9444 18s2 Variations on Backprop 25

Momentum (8.3)

If landscape is shaped like a "rain gutter", weights will tend to oscillate without much improvement.

Solution: add a momentum factor

$$\delta w \leftarrow \alpha \, \delta w + (1 - \alpha) \frac{\partial E}{\partial w}$$
$$w \leftarrow w - \eta \, \delta w$$

Hopefully, this will dampen sideways oscillations but amplify downhill motion by $\frac{1}{1-\alpha}$.

COMP9444 © Alan Blair, 2017-18
