Probability (3.1)

Begin with a set Ω – the sample space (e.g. 6 possible rolls of a die) Each $\omega \in \Omega$ is a sample point/possible world/atomic event

A probability space or probability model is a sample space with an assignment $P(\omega)$ for every $\omega \in \Omega$ such that

$$0 \le P(\omega) \le 1$$

 $\sum_{\omega} P(\omega) = 1$
e.g. $P(1) = P(2) = P(3) = P(4) = P(5) = P(6) = \frac{1}{6}.$

Outline

- Probability and Random Variables (3.1-3.2)
- Probability for Continuous Variables (3.3)
- **Gaussian Distribution (3.9.3)**
- Conditional Probability (3.5)
- Bayes' Rule (3.11)
- Entropy and KL-Divergence (3.13)
- Cross Entropy (3.13)
- Maximum Likelihood (5.5)
- Weight Decay (5.2.2)
- Momentum (8.3)

COMP9444

Probability and Backprop Variations

Random Events

A random event A is any subset of Ω

$$P(A) = \sum_{\{\omega \in A\}} P(\omega)$$

e.g.
$$P(\text{die roll} < 5) = P(1) + P(2) + P(3) + P(4) = \frac{1}{6} + \frac{1}{6} + \frac{1}{6} + \frac{1}{6} = \frac{2}{3}$$

©Alan Blair, 2017-19

COMP9444 19t3

Random Variables (3.2)

A random variable is a function from sample points to some range (e.g. the Reals or Booleans)

For example, Odd(3) = true

P induces a probability distribution for any random variable *X*:

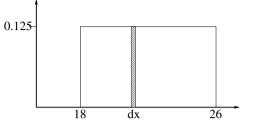

$$P(X = x_i) = \sum_{\{\omega: X(\omega) = x_i\}} P(\omega)$$

e.g.,
$$P(\text{Odd} = \text{true}) = P(1) + P(3) + P(5) = \frac{1}{6} + \frac{1}{6} + \frac{1}{6} = \frac{1}{2}$$

Gaussian Distribution (3.9.3)

e.g.
$$P(X = x) = U[18, 26](x)$$
 = uniform density between 18 and 26

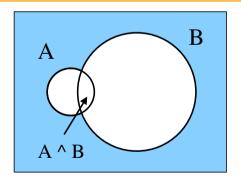

Here *P* is a density; it integrates to 1. P(X = 20.5) = 0.125 really means

 $\lim_{dx \to 0} P(20.5 \le X \le 20.5 + dx)/dx = 0.125$

Probability and Logic

Logically related events must have related probabilities For example, $P(A \lor B) = P(A) + P(B) - P(A \land B)$

 $\sigma =$ standard deviation Multivariate Gaussian: $P_{\mu\sigma}$

 $P_{\mu,\sigma}(x) = \frac{1}{\sqrt{2\pi\sigma}} e^{-(x-\mu)^2/2\sigma^2}$

 $P_{\mu,\sigma}(x) = \prod_i P_{\mu_i,\sigma_i}(x_i)$

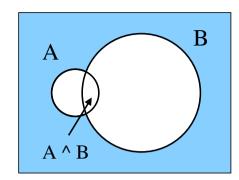

σ

0

©Alan Blair, 2017-19

 $\mu = \text{mean}$

Conditional Probability (3.5)

If $P(B) \neq 0$, then the conditional probability of A given B is

$$P(A \mid B) = \frac{P(A \land B)}{P(B)}$$

Probability and Backprop Variations

Example: Medical Diagnosis

Question: Suppose we have a test for a type of cancer which occurs in 1% of patients. The test has a sensitivity of 98% and a specificity of 97%. If a patient tests positive, what is the probability that they have the cancer?

Answer: There are two random variables: Cancer (true or false) and Test (positive or negative). The probability is called a prior, because it represents our estimate of the probability before we have done the test (or made some other observation). The sensitivity and specificity are interpreted as follows:

P(positive | cancer) = 0.98, and $P(\text{negative} | \neg \text{cancer}) = 0.97$

Bayes' Rule (3.11)

The formula for conditional probability can be manipulated to find a relationship when the two variables are swapped:

$$P(A \land B) = P(A | B)P(B) = P(B | A)P(A)$$

$$\rightarrow$$
 Bayes' rule $P(A|B) = \frac{P(B|A)P(A)}{P(B)}$

This is often useful for assessing the probability of an underlying cause after an effect has been observed:

$$P(\text{Cause}|\text{Effect}) = \frac{P(\text{Effect}|\text{Cause})P(\text{Cause})}{P(\text{Effect})}$$

Example: Light Bulb Defects

Question: You work for a lighting company which manufactures 60% of its light bulbs in Factory A and 40% in Factory B. One percent of the light bulbs from Factory A are defective, while two percent of those from Factory B are defective. If a random light bulb turns out to be defective, what is the probability that it was manufactured in Factory A?

Answer: There are two random variables: Factory (A or B) and Defect (Yes or No). In this case, the prior is:

 $P(A) = 0.6, \qquad P(B) = 0.4$

The conditional probabilities are:

P(defect | A) = 0.01, and P(defect | B) = 0.02

Probability and Backprop Variations

Entropy and KL-Divergence (3.13)

The entropy of a discrete probability distribution $p = \langle p_1, \dots, p_n \rangle$ is

$$H(p) = \sum_{i=1}^{n} p_i \left(-\log_2 p_i\right)$$

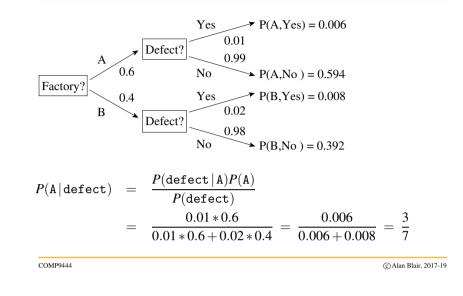

Given two probability distributions $p = \langle p_1, \dots, p_n \rangle$ and $q = \langle q_1, \dots, q_n \rangle$ on the same set Ω , the Kullback-Leibler Divergence between p and q is

$$D_{\mathrm{KL}}(p \| q) = \sum_{i=1}^{n} p_i (\log_2 p_i - \log_2 q_i)$$

KL-Divergence is like a "distance" from one probability distribution to another. But, it is not symmetric.

$$D_{\mathrm{KL}}(p \, \| \, q) \neq D_{\mathrm{KL}}(q \, \| \, p)$$

Probability and Backprop Variations

Entropy and Huffmann Coding

Entropy is the number of bits per symbol achieved by a (block) Huffman Coding scheme.

Example 1: H((0.5, 0.5)) = 1 bit.

Suppose we want to encode, in zeros and ones, a long message composed of the two letters A and B, which occur with equal frequency. This can be done efficiently by assigning A=0, B=1. In other words, one bit is needed to encode each letter.

14

COMP9444

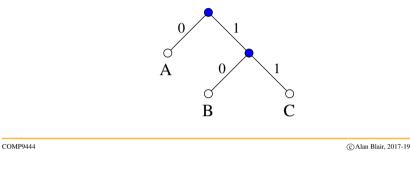

© Alan Blair, 2017-19

18

Entropy and Huffmann Coding

Example 2: $H(\langle 0.5, 0.25, 0.25 \rangle) = 1.5$ bits.

Suppose we need to encode a message consisting of the letters A, B and C, and that B and C occur equally often but A occurs twice as often as the other two letters. In this case, the most efficient code would be A=0, B=10, C=11. The average number of bits needed to encode each letter is 1.5.

Continuous Entropy and KL-Divergence

the entropy of a continuous distribution p() is

Probability and Backprop Variations

 $H(p) = \int_{\Theta} p(\theta)(-\log p(\theta)) d\theta$

Entropy and KL-Divergence

If the samples occur in some other proportion, we would need to "block" them together in order to encode them efficiently. But, the average number of bits required by the most efficient coding scheme is given by

$$H(\langle p_1,\ldots,p_n\rangle)=\sum_{i=1}^n p_i(-\log_2 p_i)$$

 $D_{KL}(p || q)$ is the number of extra bits we need to trasmit if we designed a code for q() but it turned out that the samples were drawn from p() instead.

$$D_{\mathrm{KL}}(p \| q) = \sum_{i=1}^{n} p_i (\log_2 p_i - \log_2 q_i)$$

COMP9444 19t3

Reverse KL-Divergence

KL-Divergence in Deep Learning

- KL-Divergence is used in a number of deep learning algorithms, including Variational Autoencoders (Week 10)
- KL-Divergence is also used in some policy-based deep reinforcement learning algorithms such as Variational Inference or Trust Region Policy Optimization (TPRO) (but we will not cover these in detail)

For classification tasks, target t is either 0 or 1, so better to use

 $E = -t \log(z) - (1-t) \log(1-z)$

This can be justified mathematically, and works well in practice -

 $\frac{\partial E}{\partial z} = \frac{z-t}{z(1-z)}$

 $\frac{\partial E}{\partial s} = \frac{\partial E}{\partial z} \frac{\partial z}{\partial s} = z - t$

if $z = \frac{1}{1+e^{-s}}$,

especially when negative examples vastly outweigh positive ones.

It also makes the backprop computations simpler

Variations on Backprop

Cross Entropy

- problem: least squares error function not suitable for classification, where target = 0 or 1
- mathematical theory: maximum likelihood
- ▶ solution: replace with cross entropy error function
- Weight Decay
 - ▶ problem: weights "blow up", and inhibit further learning
 - ▶ mathematical theory: Bayes' rule
 - solution: add weight decay term to error function
- Momentum
 - ▶ problem: weights oscillate in a "rain gutter"
 - ▶ solution: weighted average of gradient over time

COMP9444

Cross Entropy

X

X

Maximum Likelihood (5.5)

H is a class of hypotheses

P(D | h) = probability of data D being generated under hypothesis $h \in H$.

 $\log P(D|h)$ is called the likelihood.

ML Principle: Choose $h \in H$ which maximizes this likelihood, i.e. maximizes P(D|h) [or, maximizes $\log P(D|h)$]

In our case, each hypothesis h is a choice of parameters for a neural network or other function applied to input values x while the observed data D consist of the target values t.

Derivation of Least Squares

Suppose the data are generated by a linear function f() plus Gaussian noise with mean zero and standard deviation σ .

$$P(D|h) = P(t|f) = \prod_{i} \frac{1}{\sqrt{2\pi\sigma}} e^{-\frac{1}{2\sigma^2}(t_i - f(x_i))^2}$$

$$\log P(t|f) = \sum_{i} -\frac{1}{2\sigma^2}(t_i - f(x_i))^2 - \log(\sigma) - \frac{1}{2}\log(2\pi)$$

$$f_{ML} = \operatorname{argmax}_{f \in H} \log P(t|f)$$

$$= \operatorname{argmin}_{f \in H} \sum_{i} (t_i - f(x_i))^2$$

(Note: we do not need to know σ)

Derivation of Cross Entropy (3.9.1)

For classification tasks, t is either 0 or 1. Assume t is generated by hypothesis f as follows:

Least Squares Line Fitting

f(x)

$$P(1 | f(x_i)) = f(x_i)$$

$$P(0 | f(x_i)) = (1 - f(x_i))$$
e.
$$P(t_i | f(x_i)) = f(x_i)^{t_i} (1 - f(x_i))^{(1 - t_i)}$$

then

i.

$$\log P(t|f) = \sum_{i} t_{i} \log f(x_{i}) + (1 - t_{i}) \log(1 - f(x_{i}))$$

$$f_{ML} = \operatorname{argmax}_{f \in H} \sum_{i} t_{i} \log f(x_{i}) + (1 - t_{i}) \log(1 - f(x_{i}))$$

(Can also be generalized to multiple classes.)

COMP9444 19t3

Bayesian Inference

H is a class of hypotheses

Bayes' Theorem:

P(h) is called the prior.

Momentum (8.3)

without much improvement.

Solution: add a momentum factor

P(D|h) = probability of data *D* being generated under hypothesis $h \in H$. P(h|D) = probability that *h* is correct, given that data *D* were observed.

P(h|D)P(D) = P(D|h)P(h)

If landscape is shaped like a "rain gutter", weights will tend to oscillate

 $\delta w \leftarrow \alpha \, \delta w - \eta \, \frac{\partial E}{\partial w}$

 $w \leftarrow w + \delta w$

Hopefully, this will dampen sideways oscillations but amplify downhill

 $P(h|D) = \frac{P(D|h)P(h)}{P(D)}$

Weight Decay (5.2.2)

Sometimes we add a penalty term to the loss function which encourages the neural network weights w_i to remain small:

$$E = \frac{1}{2} \sum_{i} (z_i - t_i)^2 + \frac{\lambda}{2} \sum_{j} w_j^2$$

This can prevent the weights from "saturating" to very high values.

It is sometimes referred to as "elastic weights" because the weights experience a force as if there were a spring pulling them back towards the origin according to Hooke's Law.

The scaling factor λ needs to be determined from experience, or empirically.

COMP9444 19t3	Probability and Backprop Variations		30	COMP9444 19t3	Probability and Backprop Variations	

Weight Decay as MAP Estimation (5.6.1)

We assume a Gaussian prior distribution for the weights, i.e.

Then

$$P(w) = \prod_{j} \frac{1}{\sqrt{2\pi\sigma_{0}}} e^{-w_{j}^{2}/2\sigma_{0}^{2}}$$

$$P(w|t) = \frac{P(t|w)P(w)}{P(t)} = \frac{1}{P(t)} \prod_{i} \frac{1}{\sqrt{2\pi\sigma_{0}}} e^{-\frac{1}{2\sigma^{2}}(z_{i}-t_{i})^{2}} \prod_{j} \frac{1}{\sqrt{2\pi\sigma_{0}}} e^{-w_{j}^{2}/2\sigma_{0}^{2}}$$

$$\log P(w|t) = -\frac{1}{2\sigma^{2}} \sum_{i} (z_{i}-t_{i})^{2} - \frac{1}{2\sigma_{0}^{2}} \sum_{j} w_{j}^{2} + \text{constant}$$

$$w_{\text{MAP}} = \operatorname{argmax}_{w \in H} \log P(w|t)$$

$$= \operatorname{argmin}_{w \in H} \left(\frac{1}{2} \sum_{i} (z_{i}-t_{i})^{2} + \frac{\lambda}{2} \sum_{j} w_{j}^{2}\right)$$

where $\lambda = \sigma_0^2 / \sigma^2$.

COMP9444

motion by $\frac{1}{1-\alpha}$.
